## Abstract

Hydropower plants and large storage reservoirs upstream of water-dependent power plants represent physical assets with a substantial role in the function of both river and power grid systems. Hydropower has the potential to play an important role in decarbonization strategies as a means to achieve reliability and resilience in an increasingly complex grid; for example, as a means to offset variability in other renewable resources and provide long term energy storage. The power grid and river systems are interlinked through hydropower plants, resulting in hydropower operators needing to balance potentially competing interests of water management, as well as power demands. Despite this multisectoral dependency, the representation of hydropower in power system resource adequacy studies typically differs from the representation in water management adaptation studies, especially at the regional scale. The objective of this presentation is to clarify the concept of hydropower flexibility (and adaptation) in a way that can bridge gaps between the tools used by and expectations of water managers, hydropower operators and power system operators. The developed qualitative multisystem, multiscale approach to hydropower flexibility can be leveraged to highlight the value, facilitate the compatibility and complementarity, and inform on the generalization of technology innovation and climate change adaptation strategies.

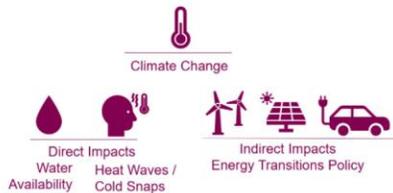

# Diversity in Approaches to Hydropower Flexibility in Water and Power System Adaptation Strategies Under Climate Change Conditions

## Climate Change Impacts and Policy Require Hydropower Adaptation

Hydropower flexibility will play an important role in decarbonization strategies while also being impacted by the direct impact of climate change on water resources.

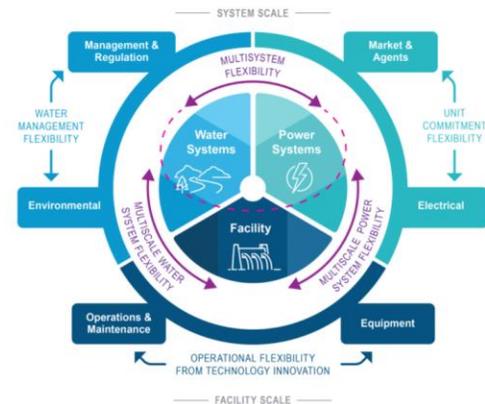

## Flexibility Objectives Differ Across Adaptation Studies

## Flexibility As An Engineering Design takes Multiple Definitions Across Hydropower Systems and Scales.

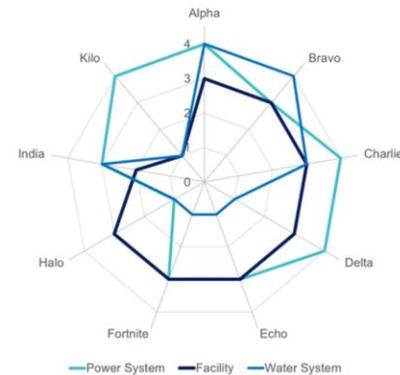

Water and Power systems are connected through hydropower plants. Adaptation Studies need to specify which flexibility they advance, e.g. flexibility of what to what.

## A Framework to Describe the Advances in Hydropower Modeling Across Water-Power Grid Studies

- Observed static boundary conditions**  
Water system: observed flow  
Power system: observed energy prices  
Facility: observed unit generation, inertia, etc
- Simulated static boundary conditions**  
Water system: simulated flow, no water management  
Power system: simulated energy prices  
Facility: simulated plant specific operations  
→ ability to perturb boundary conditions
- Simplified dynamics, in process and/or scale**  
Water system: simulated hydrology and water management with rule curves  
Power system: zonal model, or nodal with limited number of nodes  
Facility: process-based simulations of operations (e.g. penstock capacity, etc)  
→ ability to perturb processes, limited responses
- Operational complex dynamics**  
Water system: optimized water management across a river basin  
Power system: stochastic optimization for over 1,000 nodes  
Facility: unit loading optimization, controls, maintenance, etc.  
→ perturbations and system responses in an operational setting

Hydropower representations in 9 anonymized flexibility studies with an engineering design perspective. Gaps represent challenges in immediate transferability across studies despite all advance flexibility of hydropower.

## Extended Framework to Identify Gaps and Opportunities in Hydropower Adaptation Research

To integrate and transfer insight and methods across adaptation studies, application and regional characteristics also need to be specified

## Moving forward

A systematic approach to categorizing and contextualizing Water-Power Grid Adaptation projects is needed to identify synergies and gaps across projects and inform collaborative opportunities and future research priorities.

**Acknowledgements:** The mission of the HydroWIREs (Water Innovation for a Resilient Electricity System) initiative from the US Department of Energy - Water Power Technologies Office is to understand, enable and improve hydropower's contributions to reliability, resilience, and integration in the rapidly evolving U.S. electricity system. We also thank the PIs of the 14 participating HydroWIREs projects.
