Abstract

We developed a numerical thermodynamics laboratory called "Thermolab" to study the effects of the thermodynamic behavior of non-ideal solution models on reactive transport processes in open systems. The equations of state of internally consistent thermodynamic datasets are implemented in MATLAB functions and form the basis for calculating Gibbs energy. A linear algebraic approach is used in Thermolab to compute Gibbs energy of mixing for multi-component phases to study the impact of the non-ideality of solution models on transport processes. The Gibbs energies are benchmarked with experimental data, phase diagrams and other thermodynamic software. Constrained Gibbs minimization is exemplified with MATLAB codes and iterative refinement of composition of mixtures may be used to increase precision and accuracy. All needed transport variables such as densities, phase compositions, and chemical potentials are obtained from Gibbs energy of the stable phases after the minimization in Thermolab. We demonstrate the use of precomputed local equilibrium data obtained with Thermolab in reactive transport models. In reactive fluid flow the shape and the velocity of the reaction front vary depending on the non-linearity of the partitioning of a component in fluid and solid. We argue that non-ideality of solution models has to be taken into account and further explored in reactive transport models. Thermolab Gibbs energies can be used in Cahn-Hilliard models for non-linear diffusion and phase growth. This presents a transient process towards equilibrium and avoids computational problems arising during precomputing of equilibrium data.

Key Points:

- Thermolab: a set of MATLAB codes is presented to perform equilibrium and non-equilibrium thermodynamic calculations.

- Local thermodynamic equilibrium is used to study effects o non-ideality of solution models non-linear transport processes.

- Non-linear diffusion processes are investigated with Thermolab providing a transient natural physical process towards equilibrium.

Abstract

We developed a numerical thermodynamics laboratory called "Thermolab" to study the effects of the thermodynamic behavior of non-ideal solution models on reactive transport processes in open systems. The equations of state of internally consistent thermodynamic datasets are implemented in MATLAB functions and form the basis for calculating Gibbs energy. A linear algebraic approach is used in Thermolab to compute Gibbs energy of mixing for multi-component phases to study the impact of the non-ideality of solution models on transport processes. The Gibbs energies are benchmarked with experimental data, phase diagrams and other thermodynamic software. Constrained Gibbs minimization is exemplified with MATLAB codes and iterative refinement of composition of mixtures may be used to increase precision and accuracy. All needed transport variables such as densities, phase compositions, and chemical potentials are obtained from Gibbs energy of the stable phases after the minimization in Thermolab. We demonstrate the use of precomputed local equilibrium data obtained with Thermolab in reactive transport models. In reactive fluid flow the shape and the velocity of the reaction front vary depending on the non-linearity of the partitioning of a component in fluid and solid. We argue that non-ideality of solution models has to be taken into account and further explored in reactive transport models. Thermolab Gibbs energies can be used in Cahn-Hilliard models for non-linear diffusion and phase growth. This presents a transient process towards equilibrium and avoids computational problems arising during precomputing of equilibrium data.

Plain Language Summary

The behavior of Earth materials, rocks, minerals, melts, fluids and gases is important to predict physical processes in the Earth with computer models. The purpose of this is to study how the changes of variables such as fluid and solid composition influence the diffusion, fluid flow and reaction in rocks. Here we present a set of computer codes, called Thermolab, to calculate important physical properties such as density and chemical composition of solids, fluids and melts in chemical equilibrium. The calculations are based on the Gibbs energy that exists for every material. We use computer codes, written in MATLAB/OCTAVE language, to show how this Gibbs energy is calculated and used to compute chemical equilibrium and find the physical properties such as density, and chemical composition. We discuss techniques for accurate calculation of chemical equilibrium and physical properties in real rocks. Finally, we use Thermolab to formulate a computer model of fluids reacting with rocks. We find that chemical composition of the fluid and rock strongly affect the speed and shape of the boundary between reacted and unreacted rock. Thermolab can be used in phase growth models to investigate the way in which rocks develop towards equilibrium.

1 Introduction

One of the primary goals in Earth Science is to understand the physical processes that govern natural phenomena. This will facilitate prediction of potential hazardous events, such as earthquakes, volcanic eruptions, and related threats such as tsunamis (Fagents et al., 2013; Geller, 1997; Rundle et al., 2021; Ulrich et al., 2019). Predicting causes and effects of climate change, the reduction of global warming by storing CO_2, or the safety of storing nuclear waste, strongly rely on the understanding of underlying coupled physical processes (Orr, 2018; X. Zhang et al., 2022). Furthermore, the exploration of fossil fuels and raw materials in economic ore deposits, and most importantly the transition to renewable energy rely on a good understanding of the physics of geological processes (Feng et al., 2021; Vehling et al., 2020;

60 Weis et al., 2012). In many cases, numerical models that solve the mathematical equations
61 governing the physics are the only way to predict such natural processes. Even though most
62 coupled natural processes are non-equilibrium processes, the local equilibrium thermodynamic
63 assumption is needed to close the system of mass, momentum, and energy equations and
64 construct the model (De Groot & Mazur, 1984; Lebon et al., 2008). Without the knowledge of
65 thermodynamic behavior of rocks, minerals, melts, fluids and gases involved in the process
66 quantitative and predictive models cannot be constructed.

67 Transport processes such as diffusion, advection, and deformation, play a major role in
68 all the important topics and are nearly always coupled to chemical reactions. Thus, reactive
69 transport models have been a subject of geoscience research for many years (Steefel, 2019;
70 Steefel et al., 2005). A large number of reactive transport codes has been developed particularly
71 with the focus of subsurface processes (Kulik et al., 2012; Steefel et al., 2014), and applied to
72 relevant geological problems in the subsurface (e. g. Sonnenthal et al., 2005; Wanner et al.,
73 2014). A thorough review of the vast amount of work on reactive transport would be too
74 extensive for the scope of this paper. For an overview of the main reactive transport codes in use
75 for subsurface processes see Steefel et al. (2014).

76 Natural observations on, for example, exposed mantle rocks exhumed from great depth
77 can be used to learn something about natural processes of CO_2 sequestration (Kelemen & Matter,
78 2008) and may lead to new insights for human carbon storage. In this context, knowledge of the
79 thermodynamic behavior of minerals is also important for industrial processes and may lead to
80 useful discoveries for example for carbon sequestration (Glasser et al., 2016).

81 Large scale geodynamic processes influence processes at the Earth's surface and play a
82 role in the global geochemical cycles, the water budget, melt generation at ocean ridges and in
83 collision zones, and erosion in mountain belts. In subduction zones these processes are closely
84 interconnected as dehydration of hydrated oceanic lithosphere generates fluids that may trigger
85 earthquakes and induce melting in the mantle wedge that may ultimately lead to volcanism at the
86 surface, including direct effects on climate (Bebout et al., 2018). Numerical models have been
87 useful in gaining more understanding of the physical processes of migration fluids from the
88 subducting slab upwards (Wilson et al., 2014). Migration and melt focusing due to reaction
89 infiltration instabilities have been studied by Aharonov et al. (1995). Connolly (1997) showed
90 how coupling of dehydration reactions produce fluids that travel up in a visco-elastic matrix
91 creating porosity waves as a mechanism for fluid migration. Balashov and Yardley (1998)
92 investigated the effect of reaction on porosity structer and fluid pressure variation. More recent
93 models further investigated fluid focusing, transport and reaction processes (Tian & Ague,
94 2014).

95 Recent progress in some of the important topics above has been made possible by
96 coupling the local equilibrium thermodynamics to transport codes. Plümper et al. (2017) showed
97 how the initialization of dehydration in subduction zones is dominated by chemical
98 heterogeneities that control the thermodynamics on the micro-scale. Coupled to mass
99 conservation and fluid flow, these local chemical heterogeneities lead from an initially formed
100 local porosity to the development of fluid pathways.

101 The time scales of geological processes can vary between milliseconds to billion of years
102 (Beinlich et al., 2020). With the use of numerical models combined with field observations, the
103 duration of geological processes originally thought to be on the geological time scales have been

104 shown to be much faster (Ague & Baxter, 2007; Beinlich et al., 2020; John et al., 2012).
105 Therefore, the prediction of the speed of reaction fronts, and elemental transport hinges on
106 quantitative models obeying mass, momentum and energy conservation. Beinlich et al. (2020)
107 used a reactive transport code coupled to local equilibrium thermodynamics to constrain the
108 speed of natural CO_2 sequestration in serpentinites. The details behind the thermodynamic
109 calculations in Beinlich et al. (2020) are given in this paper.

110 Nonideality of the solution models and its impact on the convexity of the flow functions
111 (the so-called 'isotherms') has long been recognized as an important control on mass transport in
112 porous reactive flows (Guy, 1993; Lichtner & Carey, 2006). However, it is underexplored mostly
113 due to lack of transport models coupled to thermodynamically complex nonideal models
114 including coupled substitutions, non-convex energy functions and ordering.

115 We present a numerical thermodynamics laboratory which we shall call "Thermolab", to
116 do thermodynamic calculations on rocks, minerals, melts, and fluids involving aqueous species.
117 We further show how this can be used in reactive transport models that are based on laws of
118 mass, momentum, and energy conservation. Code examples are written in MATLAB/OCTAVE
119 as it provides a transparent way of translating the mathematics and documenting the algorithms.
120 Matlab also provides a prototype coding development platform. Short matlab codes serve as
121 'flow charts' used in the past to document the algorithms. The advantage of the
122 MATLAB/OCTAVE codes compared to the 'flow charts' is that those are actually working
123 computer programs, and can be copy-pasted from the figure and executed. Once working these
124 codes can also be easily translated to any preferred programming language for optimization and
125 supercomputing. The focus in this contribution is entirely on the technicalities with limited
126 example applications. We document the nonideality of the models and the impact on non-linear
127 transport processes in open systems by showing examples of how this can be achieved with
128 Thermolab. Future studies will be investigating the impact of the nonideality on mass transport.

2 Background and motivation

130 A typical set of equations that governs the physics of the reactive transport based on
131 Beinlich et al. (2020) is shown to motivate the use of equilibrium thermodynamics in transport
132 processes. Total mass conservation in which Darcy flux is used:

$$\frac{\partial}{\partial t}\left(\rho_f \phi + \rho_s \left(1-\phi\right)\right) = \nabla \cdot \left(\rho_f \frac{k^0 \phi^3}{\mu_f}\left(\nabla P_f + \rho_f g\right)\right) \tag{1}$$

134 Mass conservation of an immobile species in the solid:

$$\frac{\partial}{\partial t}\left(\rho_s C_{s_{im}}\left(1-\phi\right)\right) = 0 \tag{2}$$

136 Mass concentration balance of a mobile species in the fluid:

$$\frac{\partial}{\partial t}\left(\rho_f \varphi C_f + \rho_f \left(1-\varphi\right)C_s\right) - \nabla \bullet \left(\rho_f C_f \frac{k^0 \varphi^3}{\mu_f}\left(\nabla P_f + \rho_f g\right)\right) = \nabla \bullet \left(\rho_f \varphi C_f D_{C_f} \nabla \mu_{C_f}\right) \tag{3}$$

138 From this set of equations, we need to compute the local solid density, fluid density,
139 chemical potential, mobile species concentration in fluid, and in solid, and one immobile species

140 concentration in solid. When the transport of material in the fluid is neglected, the third equation
141 is omitted and the system reduces to the set of equations of Plümper et al. (2017). In any case,
142 fluid and minerals have variable composition and density. This leaves a system of three
143 equations for eight unknowns: fluid and solid density (ρ_f), and (ρ_s), weight fraction of a mobile
144 component in fluid and solid (C_f), and (C_s), chemical composition of the component in the fluid
145 (μ_{Cf}), and the weight fraction of an immobile component in the solid ($C_{s,im}$), porosity (ϕ), and
146 fluid pressure (P_f). Background permeability (k^0), fluid viscosity (μ_f) and diffusion coefficient of
147 mobile component C_f in the fluid (D_{Cf}) are given. Porosity, fluid pressure and either the fluid or
148 the solid composition of each component in the system are not thermodynamically constrained
149 and the three equations are solved for ϕ, P_f and C_s. The remaining unknown solid and fluid
150 compositions and densities are found from thermodynamic relationships assuming local
151 equilibrium at each point in time and in space in the model. In complex mineral, melt and fluid
152 solutions, the non-ideal mixing behaviour leads to non-linear thermodynamic relationships. We
153 compute these relationships with Thermolab, benchmarked with phase diagrams for rocks, fluids
154 and melts. Using MATLAB codes, the first part of this contribution documents the technical
155 details of the equilibrium thermodynamic calculations and the treatment of solid solutions. This
156 is considered essential to understand the effects on non-linear transport processes. We include a
157 description of methods to sufficiently resolve the equilibrium compositions and densities of the
158 involved phases. This is needed to avoid numerical artefacts and instability in the transport
159 codes. In the last part, we get back to the details of the implementation and solution of a system
160 of transport equations in which all quantities evolve through time. For a full list of symbols and
161 notation see Table 1.

162 Table 1 List of symbols and abbreviations. Symbols in italics for scalar variables, bold font for
163 vectors, and bold capitals to denote matrices.

Symbol	Meaning	Units	MATLAB
ρ_f	Density of fluid	kg/m^3	`rhof`
ρ_s	Density of solid	kg/m^3	`rhos`
φ	Porosity (volume fraction of fluid)	volume fraction	`phi`
C_f	Concentration of component in fluid	weight fraction	`Cf`
C_s	Concentration of component in solid	weight fraction	`Cs`
k^0	background permeability	m^2	`k0`
μ_f	fluid viscosity	Pa s	`muf`
P_f	fluid pressure	Pa	`Pf`
t	time	s	`t`
g	gravitational acceleration	m/s^2	`grav`
D_{Cf}	diffusion coefficient of component in fluid	m^2/s	`DCf`
μ_{Cf}	Chemical potential of component in fluid	J/mol	`mu_Cf`
$C_{s,im}$	concentration of immobile component in solid	weight fraction	`Cs_im`
g^0	Specific endmember gibbs energy	J/mol	`G`
s^0	Specific endmember entropy	J/mol	`S`
h^0	Enthalpy	J/mol	`H`
T	Temperature	K	`T`
P	Pressure	kbar	`P`
R	Universal gas constant	J/mol/K	`R`
g^0_r	Specific endmember gibbs energy at 1 bar, 25 °C	J/mol	`Gr`
s^0_r	Entropy at reference conditions (1 bar, 25 °C)	J/mol	`Sr`
h^0_r	Enthalpy at reference conditions (1 bar, 25 °C)	J/mol	`Hr`
v^0_r	Volume at reference conditions (1 bar, 25 °C)	J/bar	`Vr`
a	heat capacity coefficient	kJ/K	`a`
b	heat capacity coefficient	kJ/K^2	`b`

c	heat capacity coefficient	kJ K	`c`
d	heat capacity coefficient	kJ K$^{-1/2}$	`d`

b_{MRK}	Fluid EOS coefficient	kJ kbar^{-1} mol^{-1}	`b`
K	bulk modulus	kbar	`k`
K'	derivative of bulk modulus	kbar	`kp`
c_P	Heat capacity	J/mol/K	`Cp`
v	Stoiciometric coefficents in chemical reaction	mol	`v`
G_{sys}	Gibbs energy of system	J	`Gsys`
g_{mix}	Specific gibbs energy of a mixture	J/mol	`gmix`
g_{mech}	Specific gibbs energy of a mechanical mixing	J/mol	`gmech`
g_{id}	Specific gibbs energy of a ideal mixing	J/mol	`gid`
g_{nid}	Specific gibbs energy of a non-ideal mixing	J/mol	`gnid`
p	Vector of proportions of endmember in a mixture	mol fraction	`p`
m	Site multiplicity in ideal mixing energy	mol	`mtpl`
z	Vector of site fraction in a mixture	mol fraction	`z`
S_t	Site occupancy table	mol	`st`
Z_t	Site fraction endmember matrix	mol fraction	`zt`
K_{eq}	Equilibrium constant	-	`Keq`
ΔG^0_{rxn}	Difference in g^0 between products and reactants	J	`dGrxn`
α	Molar amount of phase from Gibbs minimization	mol	`alph`
$\mathbf{N_{phs}}$	Matrix of composition of phases in mol	mol	`Nphs`
$\mathbf{n_{sys}}$	Vector of system compositions in mol	mol	`nsys`
V_{mol}	Molar volume	m^3/mol	`Vmol`
$\mathbf{m_{mol}}$	Molar mass of phase vector	kg/mol	`Mmol`
$\mathbf{molm}$	Molar mass of components vector	kg/mol	`molm`
ρ	Density of a phase	kg/m^3	`rho`
ϕ_p	Volume fraction of phase	-	`phi_p`
ϕ_{mol}	Mole fraction of phase	-	`phi_m`
ϕ_{wt}	Weight fraction of phase	-	`phi_wt`
$\mathbf{\rho_{ss}}$	Vector of densities of solids	kg/m^3	`rho(solid_id)`
$\mathbf{\phi_{ss}}$	Vector of volume fraction of solids	-	`phi_p(solid_id)`
ρ_{tot}	Total density	kg/m^3	`rho_t`
β_e	Effective compressibility	Pa^{-1}	`beta_e`
μ_1	Chemical potential of component 1	J/mol	`mu_1`
D_{Cs}	Diffusion coefficient in solid	m^2/s	`Dc_s`
γ	Cahn-Hilliard surface energy parameter	J/mol	`gam`

3 Gibbs energy calculation

164

165   The starting point of equilibrium thermodynamic calculations in Thermolab is the Gibbs
166   energy of a mineral, melt, or fluid. All other required properties are derived from the Gibbs
167   energy. The calculation of Gibbs energies requires in the first place an internally consistent
168   thermodynamic dataset for pure solids, fluids, gases, or aqueous species, often referred to as
169   endmembers. Secondly, it needs solution models that describe the energy of mixing between
170   endmembers dissolved in a phase, also referred to as mixing models or activity-composition
171   relationships (e.g. Ganguly, 2020; Holland & Powell, 2003). Thermolab currently has built in
172   several internally consistent thermodynamic datasets for minerals, melts and fluids, the most
173   extensive and up to date are the Holland and Powell endmember databases (Holland & Powell,
174   1998, 2011). The SUPCRT (dslop98) mineral database (Helgeson et al., 1978; Johnson et al.,
175   1992) is implemented to allow calculations with additional minerals not included in the Holland
176   and Powell datasets. For water (and/or CO_2), several equations of state (EOS) are implemented,
177   including the EOS of the International Association for the Properties of Water and Steam

178 (IAPWS) (Wagner & Pruss, 2002, revised version, 2018), the EOS of Johnson and Norton
179 (1991), Z. G. Zhang and Duan (2005), C. Zhang and Duan (2009), Pitzer and Sterner (1994), and
180 the CORK EOS, from Holland and Powell (1991). For aqueous species, we have implemented
181 the Holland and Powell (1998) formulation, and the Tanger and Helgeson (1988) formulation as
182 implemented in SUPCRT92 (Johnson et al., 1992) using the 1998 database including more than
183 1300 aqueous species. Furthermore, it includes the Deep Earth Water (DEW) model (Sverjensky
184 et al., 2014) with the recent updates and additional species from Huang & Sverjensky (2019),
185 Aranovich et al. (2020) and the Miron dataset for aqueous species (Miron et al., 2016). This
186 forms the endmember basis for use in thermodynamics of mixtures and for the local equilibrium
187 calculations. In the future, this can be extended with additional thermodynamic endmember
188 datasets. The following documents the main code as shown in an example in Figure 1.

189 3.1 Endmembers

190 The Gibbs energy of an endmember, e.g., a mineral, gas, fluid, or melt species with a
191 fixed composition, is calculated from:

192
$$g^0 = g_r^0 - \int_{T_r}^{T} s \cdot dT + \int_{P_r}^{P} v \cdot dP + g_{ex}^0 \tag{4}$$

193 An internally consistent database contains the Gibbs energy at reference conditions (g^0_r).
194 Alternatively, it holds enthalpy and entropy data from which the Gibbs energy at reference
195 conditions can be obtained:

196
$$g_r^0 = h_r^0 - T_r \cdot s_r^0 \tag{5}$$

197 The entropy at constant pressure is evaluated from:

198
$$s^0 = s_r^0 + \int_{T_r}^{T} \frac{c_P}{T} \cdot dT \tag{6}$$

199 For every endmember, an expression for heat capacity and volume is needed to evaluate
200 the above integrals and calculate the Gibbs energy.

201 3.1.1 Solids

202 An example of a heat capacity expression to be used in (6) consists of a four-parameter
203 polynomial fit to experimental heat capacity data as used in the dataset of Holland and Powell
204 (1998, 2011):

205
$$c_P = a + bT + cT^{-2} + dT^{-1/2} \tag{7}$$

206 For the pressure dependence of Gibbs energy an equation of state (EOS) is used to relate
207 volume to pressure. For example, the Murnaghan equation of state used by Holland and Powell
208 (1998):

209
$$P = P_r + \frac{K}{K'}\left[\left(\frac{v_r^0}{v^0}\right)^{K'} - 1\right]$$

41 g      = g_mech + g_id + g_nid;                                 % Gibbs energy in Joule/mol
42 % Find stable configuration (homogeneous equilibrium)
43 [gmin,id] = min(g);                                             % minimum of Gibbs energy
44 p(id,:)                                                         % corresponding endmember proportions
```

210   **Figure 1** *Thermolab code example to calculate the Gibbs energies of a phase for a given*
211   *composition at fixed temperature (T) and pressure (P). Here the example for the amphibole*
212   *model of Green et al. (2016). This code is a possible MATLAB translation of the equations and*
213   *methods documented in the Gibbs energy calculation section of the main text. The first line in the*
214   *code clears MATLAB memory and figure. In line 3 and 4 T and P are defined. Line 5 and 6*
215   *specify, respectively, for which phase to calculate the Gibbs energy and the name of the Excel*
216   *file in which the solution model data is stored. Line 7 specifies the name of the elements in the*
217   *phase, and line 8 the corresponding composition in moles for which to calculate the Gibbs*
218   *energy. Line 10 is a call to read the needed thermodynamic data. Line 12 and 13 are needed for*
219   *aqueous species and compute the density and dielectric constant of water. Line 15 to 24 compute*
220   *the Gibbs energy of the endmembers in the solution (e. g. eq. 4&11). Proportions and site*

221 *fractions are calculated in lines 26-33. Numerical errors are removed in lines 35 and 36. In*
222 *Lines 29 and 30 a grid of all possible states of order-disorder is generated for the particular*
223 *composition of the phase specified in line 8. For all these compositions the mechanical, ideal*
224 *and non-ideal mixing energy is calculated in lines 38, 39, and 40, respectively. The non-ideal*
225 *Gibbs energy, line 40, is a call to an external function that comprises a collection of non-ideal*
226 *mixing functions that can be opted. Line 43 finds the Gibbs energy that is minimum and thus*
227 *finds the state of order-disorder. Line 44 displays the corresponding proportions of the*
228 *endmembers.*

229 Note that the reference pressure is added to ensure the limit of standard reference
230 conditions. The EOS can be rearranged for volume:

$$v^0 = v_r^0 \left[1 + \left(P - P_r \right) \left(\frac{K}{K'} \right) \right]^{-\frac{1}{K'}} \tag{9}$$

232 Substituting expression (6), and (9) into (4), and using a suitable heat capacity formula
233 such as (7), the integrals can be evaluated analytically, or numerically. Lines 18-21 in Figure 1
234 show a MATLAB example of using equations (4), (5), and (6). In the example, the integrals in
235 equation (4) are evaluated in a separate function. To use a different thermodynamic database, the
236 heat capacity equation and EOS can be replaced by the appropriate expression. A number of
237 important endmembers such as quartz are treated with additional volume and entropy terms to
238 account for first or second order phase transitions such as heat capacity anomalies or order-
239 disorder in the crystal lattice (e.g. sillimanite Holland & Powell, 1996). This then requires an
240 excess Gibbs energy contribution, which in principle can also be calculated according to
241 equation (4) using different volume and heat capacities and integration limits (e.g. Berman &
242 Brown, 1985). Alternatively, an expression for this additional energy is given (Holland &
243 Powell, 1998). In the example in Figure 1, this is represented by a call to a MATLAB function
244 (line 20 in Figure 1). For the specific details we refer to the original papers documenting the
245 internally consistent databases (Berman, 1988; Holland & Powell, 1998, 2011; Johnson et al.,
246 1992).

247 3.1.2 Fluids

248 For molecular fluids such as H_2O and CO_2, the EOS, e.g. equation (8), is replaced by an
249 appropriate fluid EOS. As water is one of the most important fluids on our planet, extensive
250 work has been done on the thermodynamic formulation. The main difference between solids is
251 that the fluid EOS, especially for water, usually cannot easily be rearranged for volume as there
252 are multiple volumes possible for a single pressure in the region of coexisting fluid and gas. An
253 example of this is given by the Modified Redlich Kwong (MRK) EOS, on which Holland and
254 Powell (1991) base the fluid Gibbs energies to be compatible with the extensively used
255 thermodynamically consistent dataset of Holland and Powell (1998):

$$P = \frac{RT}{v - b_{MRK}} - \frac{a_{MRK}}{v \left(v + b_{MRK} \right) \sqrt{T}} \tag{10}$$

257 Because this is a multivalued function a suitable algorithm must be used to calculate
258 volume as function of P-T in the two-phase region (e.g. where gas and liquid coexist). In the
259 single-phase region, the volume for the stable phase (gas or liquid) should be determined.

260 Holland and Powell (1991) rearranged the equation as a cubic in volume after which the correct
261 root must be found in each phase region. Rather than solving which phase (e.g. gas, liquid, or
262 both) is stable, the different regions were predefined and the correct volume was selected based
263 on the P-T conditions. The MRK formulation in (10) is extended with a virial contribution and
264 Holland and Powell (1991), give detailed instructions how to calculate the volume as function of
265 P-T for H_2O, CO_2, and several other COH species. The advantage of the CORK formulation is
266 that it can be integrated analytically and details in the original paper of Holland and Powell
267 (1991) are sufficient for reproducing the values for use in Thermolab. The more updated
268 thermodynamically consistent dataset of Holland and Powell (2011), that replaces the Holland
269 and Powell (1998) dataset, uses the EOS of Pitzer and Sterner (1994).

270 Calculating the Gibbs energy of fluids then follows equation (4) just as for solids, with an
271 entropy integral that is consistent with the dataset for solid, melt and/or gas endmembers. The
272 Holland and Powell (1998, 2011) datasets have parameters for heat capacity, fitted
273 simultaneously with the minerals to ensure the Gibbs energy at room pressure and elevated
274 temperature can be calculated consistently.

275 In principle, the CORK or Pitzer and Sterner (1994) EOS can be used in conjunction with
276 the SUPCRT mineral database, however for the entropy integral in (4) a consistent heat capacity
277 formulation is needed to obtain thermodynamic calculations. The SUPCRT database does not
278 contain heat capacity values for H_2O. The specific details needed for this calculation in the
279 original papers of Johnson and Norton (1991) and Johnson et al. (1992) could not be found.
280 Similarly, the DEW spreadsheet does not contain H_2O entries and combines Helgeson and
281 Delaney (1978) and an internal routine for use only above at least 0.1 GPa, likely as it is intended
282 to be used for Deep Earth applications. Moreover, at low P and T, e.g. for shallow processes, the
283 CORK EOS should not be used (Holland and Powell, 1991). We found that by using the NIST
284 Shomate heat capacity equations (Shomate, 1954), using parameters from the NIST website for
285 liquid water and gas the Gibbs energies retrieved from SUPCRT can be reproduced accurately.
286 The simplicity of the formulation and up to date online documentation of the parameters is of
287 advantage. For calculations at elevated P, the numerical integration of the IAPWS or the EOS of
288 Johnson and Norton (1991) give satisfactory results at low T, whereas the CORK EOS can be
289 used above 100 °C (Holland and Powell, 1991).

290 3.1.3 Aqueous species

291 Gibbs energies of aqueous species are calculated in Thermolab following the formulation
292 of Tanger and Helgeson (1988) as also outlined in Johnson et al. (1992). The resulting Gibbs
293 energies have been compared to the output from SUPCRT and are reproduced within 1 Joule
294 precision. The DEW model (Sverjensky et al., 2014) and the Miron dataset (Miron et al., 2016;
295 Miron et al., 2017) use the same formulation, with refitted parameters for some of the
296 endmember species. Although fundamentally the aqueous species are also calculated according
297 to equation (4), there is a difference to the solid, melt and fluid endmembers because the aqueous
298 species need the density and dielectric constant of the solvent. The contribution to Gibbs energy
299 of solvation therefore needs the density and dielectric constant of water for the Born equation
300 (Figure 1, Lines 12-13). This is included in the excess Gibbs energy term (Figure 1, Line 20).
301 Note that in the example for amphibole in Figure 1, the properties of water are irrelevant, but to
302 maintain some generality they have been left in the example. When computing the Gibbs energy
303 of aqueous species, we change the name of the phase from Amphibole into any desired aqueous

304   species or fluid mixture defined in the solution model file. In Thermolab, the user can choose
305   from a number of EOS and dielectric constants to be used in the aqueous species Gibbs energy
306   (Fernández et al., 1997; Johnson & Norton, 1991; Sverjensky et al., 2014). The aqueous species
307   endmembers of Holland and Powell (1998) offers a restricted set of species compared to the
308   SUPCRT data, but it has the advantage that it is fitted in the internally consistent dataset of the
309   mineral, melt and gas endmembers of Holland and Powell (1998, 2011). Their formulation is
310   based on the Anderson density equation (Anderson et al., 1991) and uses the CORK EOS for the
311   water density. These aqueous species endmember data can also be used in fluid mixtures (Evans
312   & Powell, 2006, 2007).

313   3.1.4 Dependent endmembers

314   Endmembers can also be formed from a linear combination of several other endmembers
315   (Figure 1, Line 23):

$$g_{dep}^0 = \mathbf{v} \cdot \mathbf{g^0} \tag{11}$$

317   where the $\mathbf{v}$ holds the stoichiometric reaction coefficients. A formation energy may be associated
318   with such a reaction and this can be captured in any functional form in the excess Gibbs energy
319   term of (4).

320   3.2 Gibbs energy of mixtures

321   The Gibbs energy of a phase (mineral, gas, fluid or melt species) that can form a mixture
322   between several endmembers is represented by the sum of mechanical, ideal, and non-ideal
323   mixing energies (Figure 1, Line 41):

$$g_{mix} = g_{mech} + g_{id} + g_{nid} \tag{12}$$

325   The mechanical part of the mixing is the sum of the Gibbs energy of all endmembers in
326   the mixture, weighted by their proportions (p) (Figure 1, Line 38).

$$g_{mech} = \mathbf{p} \cdot \mathbf{g}^0 \tag{13}$$

328   The ideal mixing Gibbs energy is given by a linear combination of the site fractions in the
329   mixture multiplied with their logarithm (Figure 1, Line 39):

$$g_{id} = R T \, \mathbf{m} \cdot \left(\mathbf{z} \ln(\mathbf{z}) - \mathbf{Z_t} \ln(\mathbf{Z_t}) \cdot \mathbf{p} \right) \tag{14}$$

331   The last term in equation (14) ensures that the ideal Gibbs energy is zero in the limit of
332   the pure endmember.

333   Non-ideal Gibbs energy can be calculated in the simplest way with a binary mixing
334   formula:

$$g_{nid} = \mathbf{p^T} \cdot \mathbf{W} \cdot \mathbf{p} \tag{15}$$

336   This is essentially a sum of multiplications of binary pairs of endmembers in the mixture
337   multiplied with their interaction parameters. These interaction parameters can depend on
338   composition to get an asymmetric mixing formulation, referred to as subregular mixing model

339   (Ganguly, 2020). When **p** is replaced with a size parameter adjusted proportion and using the
340   appropriate **W** the asymmetric formulism of Holland and Powell (2003) can be used. If the molar
341   volumes of the endmembers are used as size parameter, it is essentially a Van Laar mixing model
342   (Van Laar, 1906), as for example used by Aranovich and Newton (1999). The **W** and any size
343   parameters are in general also temperature and pressure dependent such as also the molar volume
344   used in Van Laar mixing models. Any other regular or subregular solution models can be used in
345   place of (15) and ternary interaction terms may be added. In Thermolab, it is possible to expand
346   the codes with a variety of mixing formulas for the non-ideality by adding the appropriate
347   formulation to the function called in line 40 in Figure 1.

348   3.3 Solution models

349   The data for **m**, and $\mathbf{Z_t}$ are retrieved from a site occupancy table, stored for example in an
350   Excel spreadsheet. In this spreadsheet, also data for **W** and any size parameters for asymmetric
351   formalism models (Holland & Powell, 2003) and the model type are stored. In Figure 1, the data
352   is loaded in the beginning of the code (line 10, Figure 1) from a function that reads the Excel
353   data. Site fractions **z** are obtained by multiplying the transpose of the site fraction speciation
354   matrix with a column vector of proportions:

355
$$\mathbf{z} = \mathbf{Z_t}^{T} \cdot \mathbf{p} \tag{16}$$

356   After specifying proportions of the endmembers in a solution, the Gibbs energy of that
357   particular phase and composition at a given P and T can be calculated from the above.

358   3.3.1 Site occupancy

359   The site occupancy of the mixture can be represented by a table listing the occupancy of
360   crystallographic sites for each endmember. For example a binary olivine solution with only one
361   crystallographic site M, and a fixed silica tetrahedral site (which has composition SiO_4), is shown
362   in Table 2. It can be represented by a matrix:

363
$$\mathbf{S_t} = \begin{bmatrix} 2 & 0 & 1 \\ 0 & 2 & 1 \end{bmatrix} \tag{17}$$

364   Table 2. Binary olivine site occupancy

Site	M		T
Occupancy	*Mg*	*Fe*	*SiO$_4$*
Endmember			
Forsterite	2	0	1
Fayalite	0	2	1

365   The columns represent occupancy of each species on a crystallographic site for the
366   endmember in the rows of the table. Site fractions **z** can be retrieved from this table by dividing
367   each site occupancy over the sum of moles of the species on that site, which gives the site
368   multiplicity, and can be represented by a vector:

369
$$\mathbf{m} = \begin{bmatrix} 2 & 2 & 1 \end{bmatrix} \tag{18}$$

370 Elementwise division of each row in Table 2 or in matrix (17) with this multiplicity
371 vector leads to a table of site fractions represented by the matrix:

$$\mathbf{Z_t} = \begin{bmatrix} 1 & 0 & 1 \\ 0 & 1 & 1 \end{bmatrix}$$

372   (19)

373 Table 3. Binary olivine site fraction table
374

Site	M		T
Occupancy	*Mg*	*Fe*	*SiO₄*
Site multiplicity	*2*	*2*	*1*
Endmember			
Forsterite	1	0	1
Fayalite	0	1	1

375

376 Using (16) and spelling this out in matrix-vector notation, it is essentially a set of
377 equations where the coefficients in front of the proportions are directly read from the site fraction
378 table and then transposed:

$$\begin{bmatrix} z^M_{Mg} \\ z^M_{Fe} \\ z^T_{SiO_4} \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \\ 1 & 1 \end{bmatrix} \begin{bmatrix} p_{fo} \\ p_{fa} \end{bmatrix}$$

379   (20)

380 The site fractions become:

$$z^M_{Mg} = p_{fo}$$
$$z^M_{Fe} = p_{fa}$$
$$z^T_{SiO_4} = p_{fo} + p_{fa}$$

381   (21)

382 3.3.2 Ordering

383 In fact, in olivine, Mg and Fe can interchange on two molecular sites M1 and M2. We
384 could rewrite the site speciation table. However using only the two endmembers, it would not
385 lead to a different configurational entropy. There needs to be an endmember that allows different
386 distribution of Mg and Fe on the two sites. This is the purpose of introducing an ordered
387 endmember e.g. "Ordered Olivine". The Gibbs energy of this endmember can be made out of
388 two endmembers, forsterite and fayalite and an energy of reaction may be added.

389 After this, we get three proportions that define the Gibbs energy. In principle, the
390 endmember could also be formulated as having all Fe on M1 and all Mg on M2, however using a
391 negative proportion of the ordered olivine listed in the table we can also reach this result (Powell
392 & Holland, 1999).

393 Using the speciation matrix and (16) we get:

394

$$\begin{bmatrix} z_{Mg}^{M1} \\ z_{Fe}^{M1} \\ z_{Mg}^{M2} \\ z_{Fe}^{M2} \\ z_{SiO_4}^{T} \end{bmatrix} = \begin{bmatrix} 1 & 0 & 1 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 1 & 1 \\ 1 & 1 & 1 \end{bmatrix} \begin{bmatrix} p_{fo} \\ p_{fa} \\ p_{od} \end{bmatrix}$$

(22)

395   Giving the site fractions:

$$z_{Mg}^{M1} = p_{fo} + p_{od}$$

$$z_{Fe}^{M1} = p_{fa}$$

$$z_{Mg}^{M2} = p_{fo}$$

$$z_{Fe}^{M2} = p_{fa} + p_{od}$$

$$z_{SiO_4}^{T} = p_{fo} + p_{fa} + p_{od}$$

396

(23)

397   3.3.3 Worked example

398   Using the multiplicities and site fractions for the olivine example we get using Equation
399   (14):

400

$$g_{id} = R\,T\,2\left(z_{Mg}^{M} \cdot ln\left(z_{Mg}^{M}\right) + z_{Fe}^{M} \cdot ln\left(z_{Fe}^{M}\right)\right)$$

(24)

401   The non-ideal mixing energy becomes:

402

$$g_{nid} = \left(w_{fo,fa} + w_{fa,fo}\right) p_{fo}\, p_{fa}$$

(25)

403   In case we use a Holland and Powell (1998) model for olivine, the non-ideal parameters
404   are equal to each other and reduces to the simple binary symmetric mixing parabola:

405

$$g_{nid} = 2w_{fo,fa}\left(1 - p_{fo}\right) p_{fo}$$

(26)

406   For the example with order-disorder the ideal mixing Gibbs energy becomes:

407

$$g_{id} = R\,T\left(z_{Mg}^{M1}\,ln\left(z_{Mg}^{M1}\right) + z_{Fe}^{M1}\,ln\left(z_{Fe}^{M1}\right) + z_{Mg}^{M2}\,ln\left(z_{Mg}^{M2}\right) + z_{Fe}^{M2}\,ln\left(z_{Fe}^{M2}\right)\right)$$ (27)

408   (Note that the T-site fraction cancels due to the logarithms because the site fraction is
409   always 1).

410   The non-ideal Gibbs energy becomes:

411

$$g_{nid} = \left(w_{fo,fa} + w_{fa,fo}\right) p_{fo}\, p_{fa} + \left(w_{fo,od} + w_{od,fo}\right) p_{fo}\, p_{od} + \left(w_{fa,od} + w_{od,fa}\right) p_{fa}\, p_{od}$$

(28)

412   3.3.4 Proportions from site fractions

413   The proportions can be written as function of site fractions by solving the system of
414   equations in (23) using the independent equations and the fact that proportions sum up to 1. This
415   leads to:

$$z_{Fe}^{M1} = p_{fa}$$
$$z_{Mg}^{M2} = p_{fo}$$
$$p_{fo} + p_{fa} + p_{od} = 1$$

416   (29)

417   Which after solving for proportions gives:

$$p_{fa} = z_{Fe}^{M1}$$
$$p_{fo} = z_{Mg}^{M2}$$
$$p_{od} = 1 - z_{Fe}^{M1} - z_{Mg}^{M2}$$

418   (30)

419   Hence, there are two independent site fractions together completely defining the composition and
420   ordering of the olivine in this example.

421   3.3.5 Proportions from composition

422   From the olivine table we can derive a list of compositions of each endmember by
423   summing up the moles of each atom over the sites.

424   Again, this table can serve to set up a system of equations and may be added by the
425   constraint that the sum of the proportions equals 1 (first equation):

$$\begin{bmatrix} 1 & 1 & 1 \\ 2 & 0 & 1 \\ 0 & 2 & 1 \\ 1 & 1 & 1 \end{bmatrix} \begin{bmatrix} p_{fo} \\ p_{fa} \\ p_{od} \end{bmatrix} = \begin{bmatrix} 1 \\ Mg \\ Fe \\ SiO_4 \end{bmatrix}$$

426   (31)

427   However, this table only has 2 independent equations (rank = 2). We need another
428   equation to solve for all three proportions. A simple solution could be to treat the ordered
429   endmember as a known variable on the right hand side. Our extended system can be written:

$$\begin{bmatrix} 1 & 1 & 1 \\ 2 & 0 & 1 \\ 0 & 2 & 1 \\ 1 & 1 & 1 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} p_{fo} \\ p_{fa} \\ p_{od} \end{bmatrix} = \begin{bmatrix} 1 \\ Mg \\ Fe \\ SiO_4 \\ p_{od} \end{bmatrix}$$

430   (32)

431   Starting from the first required equation and adding equations until we have reached the
432   rank of the matrix gives us directly the first 2 and the last equation. This means the set of
433   independent equations becomes:

434
$$\begin{bmatrix} 1 & 1 & 1 \\ 2 & 0 & 1 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} p_{fo} \\ p_{fa} \\ p_{od} \end{bmatrix} = \begin{bmatrix} 1 \\ Mg \\ p_{od} \end{bmatrix}$$
(33)

435   The matrix in (33) can be inverted and used to find the expressions for the endmember
436   proportions as function of composition:

437
$$\begin{bmatrix} 0 & 0.5 & -0.5 \\ 1 & -0.5 & -0.5 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 \\ Mg \\ p_{od} \end{bmatrix} = \begin{bmatrix} p_{fo} \\ p_{fa} \\ p_{od} \end{bmatrix}$$
(34)

438   Instead of varying the ordered endmember proportion, it is also possible to vary one of
439   the site fractions. For example, we can have the site fraction of Fe on M2 as variable in addition
440   to the compositional variables. This way, we can fix the bulk composition of the mineral while
441   varying the site occupancies due to ordering. To this end, we add the equation for site fraction of
442   Fe on M2 (from equation (23)), to the original system of equations:

443
$$\begin{bmatrix} 1 & 1 & 1 \\ 2 & 0 & 1 \\ 0 & 2 & 1 \\ 1 & 1 & 1 \\ 0 & 1 & 1 \end{bmatrix} \begin{bmatrix} p_{fo} \\ p_{fa} \\ p_{od} \end{bmatrix} = \begin{bmatrix} 1 \\ Mg \\ Fe \\ SiO_4 \\ z_{Fe}^{M2} \end{bmatrix}$$
(35)

444   Here only the first, second, and last equation are independent and so we have:

445
$$p_{fo} + p_{fa} + p_{od} = 1$$
$$2p_{fo} + p_{od} = Mg$$
$$p_{fa} + p_{od} = z_{Fe}^{M2}$$
(36)

446   Solved for the three unknown proportions:

447
$$p_{fo} = 1 - z_{Fe}^{M2}$$
$$p_{fa} = 2 - Mg - z_{Fe}^{M2}$$
$$p_{od} = Mg + 2z_{Fe}^{M2} - 2$$
(37)

448   These equations guarantee a fixed olivine composition, while changing the distribution of
449   Fe and Mg on M1 and M2. The site fraction equation to pick as order equation can be obtained
450   by augmenting the system of equations in (35) with the site fraction equations in (23). Then from
451   this complete set of equations, we pick only the independent ones by starting from the first
452   equation in (35) and adding only equations that increase the rank of the system of equations.
453   Taking as first equation that the sum of proportions add to one (first row in eq. (35)), is
454   convenient as it guarantees the minimum amount of compositionally independent variables. A
455   Matlab code that automates this procedure is used in Thermolab. This function gives the

456 independent components for each solution model as well as the site fraction to vary as order
457 parameter and the matrix of converting composition to proportion.

458 For any given composition, there are limits on the value of z^{M2}_{Fe}. The easiest to see that
459 not any value between 0 and 1 is possible is to take pure forsterite, where Mg = 2. Then there is
460 no Fe in the olivine, and therefore z^{M2}_{Fe} can only be 0. In Thermolab, the range of possible
461 values for site fractions is found by generating the full range of values and discarding impossible
462 site fractions (below 0 and above 1).

463 We note that it is also possible to calculate site fractions from bulk composition as is
464 shown in the Appendix in Vrijmoed and Podladchikov (2015).

465 3.2.6 Aqueous fluids

466 For mixtures of aqueous species, an approach similar to the ideal olivine example can be
467 taken. Treating the fluid mixture with a one-site model in which all species mix in a similar
468 fashion the mechanical and ideal mixture is calculated as in equation (13) and (14), and for the
469 non-ideality, the Helgeson Kirkham Flowers (HKF) extended Debye-Hückel activity is used
470 (Dolejš & Wagner, 2008; Helgeson et al., 1981). The Gibbs energy of the fluid mixture are on a
471 molality scale when the formulation of Johnson et al. (1992) and the HKF activity model
472 (Helgeson et al., 1981) is used and must be converted to a molar based scale as in Dolejs (2013)
473 to be compatible with the solids. This is taken care by adding a correction term in the non-ideal
474 Gibbs energy.

4 Equilibrium calculations using reactions

476 Gibbs energies calculated with the Thermolab codes are benchmarked with
477 THERMOCALC (Holland & Powell, 2011), SUPCRT92 (Johnson et al., 1992), the DEW
478 spreadsheet (Sverjensky et al., 2014) or data and phase diagrams from the relevant publications
479 (Miron et al., 2016) and Perple_X (Connolly, 2005). Additionally, comparing with experimental
480 data is essential to increase confidence in the method.

481 With the Gibbs energies of endmembers, equilibrium conditions for simple reactions can
482 be calculated. Results for several solid state and fluid-solid reactions are shown Figure 2. The
483 curves are produced by making use of the equilibrium condition:

$$0 = \Delta G_{rxn}{}^{0} + RT \ln(K_{eq}) \tag{38}$$

485   For pure phases (e.g. endmembers), the equilibrium constant will be 1 and the
486   logarithmic term disappears leaving only $\Delta G^0_{rxn} = 0$. Using the endmember Gibbs energies and
487   stoichiometric coefficient of reactions the contour line of $\Delta G^0_{rxn} = 0$ can be plotted to visualize
488   the reaction in P-T space (Figure 2a). In a simple dissolution reaction K_{eq} will be equal to
489   solubility and so we can use ΔG^0_{rxn} to calculate the solubility of quartz (Figure 2b). An example
490   of a single dissociation reaction is shown in Figure 2c. By varying activities in K_{eq} and using
491   them as axis on a diagram the contour lines where the right hand side is 0 are used to obtain an
492   activity-activity plot (Figure (2d).
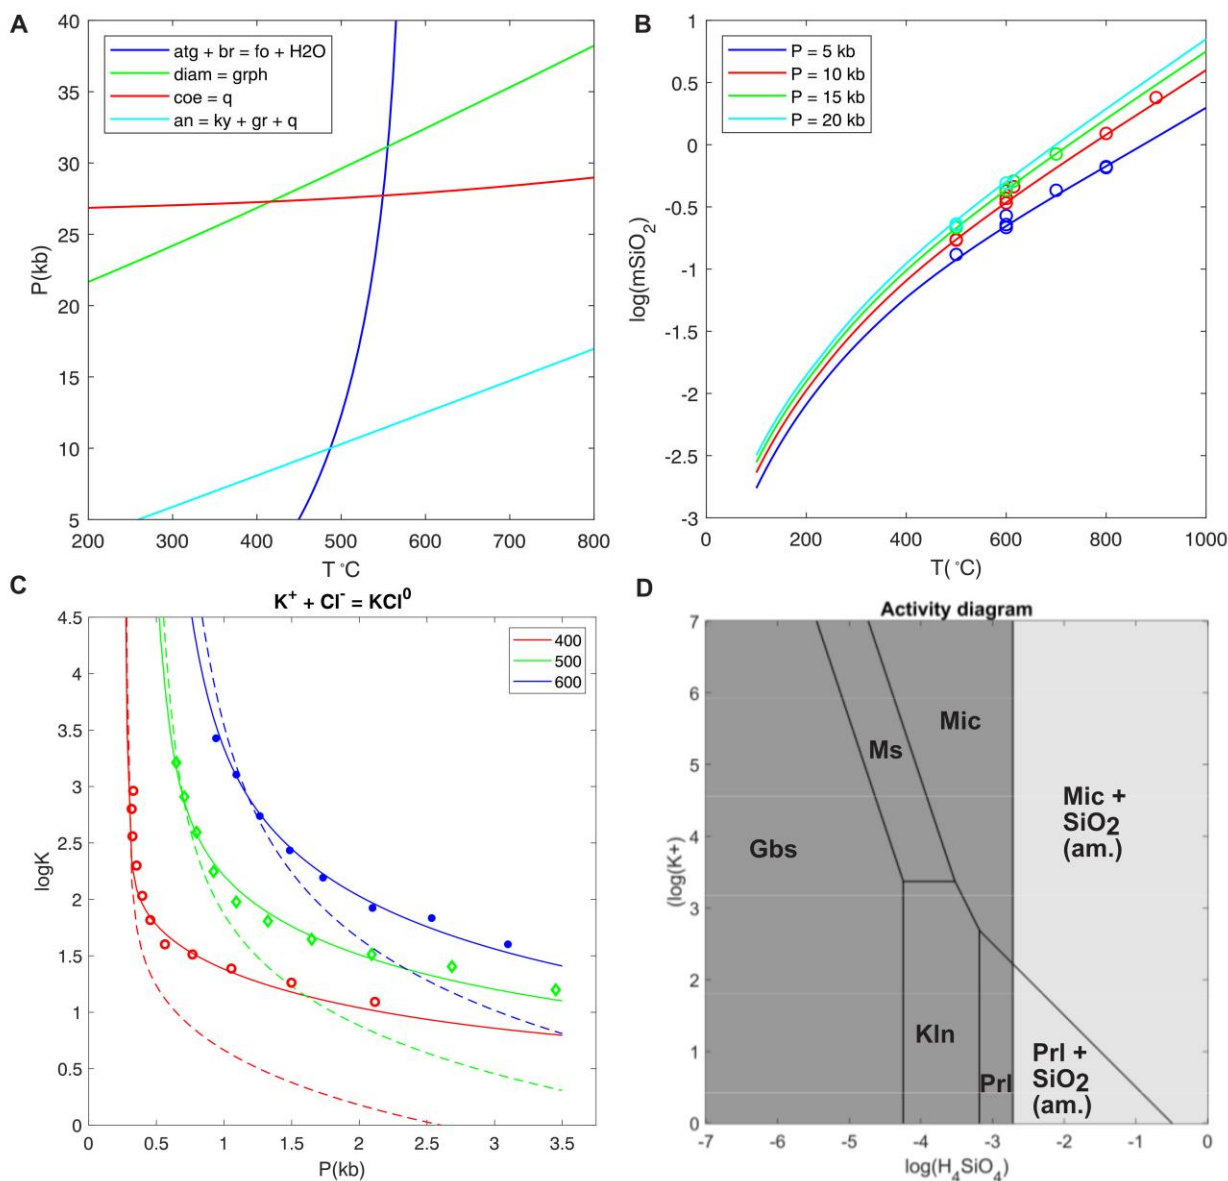

493   **Figure 2** *Example equilibrium calculations using a basic chemical reaction approach. **a)**

5 Gibbs minimization in MATLAB

508 Using the ΔG of reaction, the metastable part of individual reactions will also be plotted
509 (e.g. Figure 2a). For an equilibrium phase diagram, a Schreinemakers analysis or similar
510 procedure may follow to draw the stable reactions (e.g. Figure 2d). Additionally, the phases and
511 reactions to be calculated must be known beforehand. However, in many cases it can be desired
512 to predict which reactions may take place. Instead of predicting the equilibrium line of a
513 chemical reaction we calculate the stable phase assemblage at a point in P-T by determining
514 which mineral has the minimum Gibbs energy. In the example code (Figure 3A), the calculation
515 of Gibbs energy of the endmembers is done in line 9, a call to the main Thermolab function,
516 which includes the code in Figure 1 to focus on the minimization algorithm. If all phases have
517 the same composition (i.e. they are polymorphs), then the "min" function can be used (Figure
518 3A&B). Instead of locating the coexisting phases in a reaction in P-T-X space, the Gibbs
519 minimization delivers the stable phases everywhere except for on the reaction line. Therefore,
520 the reaction lines reflect the resolution of the P-T grid for which the Gibbs energies of each
521 phase are calculated. At sufficiently high resolution, the reaction lines become smooth.

522 Natural chemical systems, e.g., rocks, generally, are multi-component systems. In this
523 case mass balance must be considered while finding the minimum of Gibbs energy. For a more
524 thorough thermodynamic analysis of this see e.g. Connolly (2017). Constrained Gibbs energy
525 minimization is employed in the majority of phase diagram calculation software (Connolly,
526 2009; Gordon & McBride, 1994). In MATLAB, the simplest way this can be achieved is using
527 linear programming (function "linprog", e.g. Dantzig et al., 1955). With this function,
528 minimization can be done under the constraints of mass balance equalities, which for
529 completeness is shortly outlined in the following.

530 The function "linprog" is used to find the minimum Gibbs energy of the system by
531 solving the following optimization problem,

$$\min(G_{sys}) = \mathbf{g} \cdot \boldsymbol{\alpha}$$

532   (39)

533 where $\boldsymbol{\alpha}$ and $\mathbf{g}$ are vectors of respectively, the molar amount, and the Gibbs energies of
534 all phases. The "linprog" algorithm then searches for the components in $\boldsymbol{\alpha}$ that make the
535 minimum Gibbs energy of the system, while respecting the following mass balance equality:

$$\mathbf{n}_{sys} = \mathbf{N}_{phs} \cdot \boldsymbol{\alpha}$$

536   (40)

537   Which state that the sum of the amount of each phase multiplied by the composition of a
538   component should equal the sum of that component in the system. A final requirement is that no
539   negative amount α is allowed as that is physically meaningless:

540 $$\boldsymbol{\alpha} \geq 0$$ (41)

541   **Figure 3** *Two examples of Gibbs minimization to calculate phase equilibrium with*
542   *Thermolab. The Gibbs energy calculation shown in Figure 1 is used here as an external function*
543   *to improve clarity of the algorithm. a) Code showing unconstrained Gibbs minimization used to*
544   *calculate the aluminosilicate phase diagram. The Gibbs energies of the phases are obtained in*
545   *line 9, using a unique identifier to distinguish them from the same phases in another database.*
546   *Andalusite from the tc-ds55 THERMOCALC (Holland & Powell, 1998) dataset (and, tc-ds55),*
547   *kyanite (ky,tc-ds55) and sillimanite (sill,tc-ds55) in the order in which they are specified in line*
548   *5. The result is a 3D array with T in first dimension, P in second dimension and phase in third*
549   *dimension. Line 11 then finds the minimum in the 3rd dimension, which results in a value (val)*
550   *and index (ind) for each P-T. The index corresponds to the list of phases in line 5. A color coded*
551   *visualization of the phase index that gives the lowest Gibbs energy is shown to the right using the*
552   *pcolor function in MATLAB (code: line 13). The color bar indicates that the blue area has index*
553   *1, which then means it is the first phase in the list (line 5) that is stable (i. e. 1= andalusite, 2=*
554   *kyanite, 3=sillimanite). The resolution of phase diagram can be increased by decreasing the step*

*size of temperature and pressure (line 3&4). **b**) Resulting plot from code in (a). **c**) MATLAB*
example to calculate chemical equilibrium using constrained Gibbs energy minimization. For the
first lines see (a). In line 7-8 the system composition is specified using total moles of SiO₂ and
MgO. Then the phase compositions in moles is expressed in the matrix N_{phs} with in each column
the phase corresponding to the list in line 5. Each row holds the components (SiO₂, MgO). This
information is used as equality constraints in the function linprog which is called in line 14. It
then finds the minimum Gibbs energy of the system out of the 4 possible phases, while satisfying
the equality constraints. The second and third input arguments for 'linprog' are empty as they
are reserved for inequalities and the fourth and fifth arguments are for the matrix of coefficients
and right-hand side vector, respectively. To restrict the linear programming search for the
amount of each phase to positive values we input also the lower bound vector of zeros (LB), e.g.
equation (41). Then alph will hold the amount of each phase that will make minimum system
Gibbs energy while obeying system composition. The phases that have an alph above zero
*represent the equilibrium assemblage for the given P-T-X conditions. **d**) G-X diagram in which*
the Gibbs energy of the phases are plotted against system composition (for plotting the Gibbs
energy is normalized over the sum of the moles of component in each phase: i.e. the sum over the
rows of N_{phs}).

As a worked example we may consider the binary system SiO₂-MgO. Possible phases
that can be built from these components are quartz, periclase, enstatite, forsterite. Spelled out for
this case the equations read in matrix form:

$$\min(G_{sys}) = \begin{pmatrix} g_{qtz} & g_{per} & g_{en} & g_{fo} \end{pmatrix} \begin{pmatrix} \alpha_{qtz} \\ \alpha_{per} \\ \alpha_{en} \\ \alpha_{fo} \end{pmatrix} \tag{42}$$

And

$$\begin{pmatrix} N_{sys,SiO_2} \\ N_{sys,MgO} \end{pmatrix} = \begin{pmatrix} N_{qtz,SiO_2} & N_{per,SiO_2} & N_{en,SiO_2} & N_{fo,SiO_2} \\ N_{qtz,MgO} & N_{per,MgO} & N_{en,MgO} & N_{fo,MgO} \end{pmatrix} \begin{pmatrix} \alpha_{qtz} \\ \alpha_{per} \\ \alpha_{en} \\ \alpha_{fo} \end{pmatrix} \tag{43}$$

Figure 3c shows the MATLAB translation and usage of "linprog" (Figure 3c, line 14) to
calculate the stable phase assemblage. The required known values for the minimization are the
vector of Gibbs energies (Figure 3c, line 6), a vector of system compositions (Figure 3c, line 7)
with matrix of mineral compositions (Figure 3c line 10-12) as in equation (43). Note that in
Figure 3C single elements have been used as components instead of the oxides, which leads to
the same result. After defining the lower bounds of alpha's as zero, linprog finds the alpha's that
make the minimum of Gibbs energy. The results are plotted in Figure 3d and shows that for a
system composition between enstatite and forsterite, alpha's of enstatite and forsterite are non-
zero which means that those are the stable phases and the magnitude of the alpha's give the
molar amount of each stable phase in order of definition of the list of phases in Figure 3c, line 5.

588   Performing a minimization at each point in a grid of pressure and temperature and
589 evaluating at each P-T point the stable phase assemblage leads to a phase diagram in which also
590 the amount of each phase is known because of the mass balance constraint. Figure 4a shows that
591 this produces the same result in case of the pure Al_2SiO_5 system, as in the unconstrained
592 minimization, but that it can now be used to do multi-component systems such as dehydration of
593 antigorite in SiO_2, MgO, H_2O (Figure 4b).
594   **Figure 4** *a) One component system phase diagram, using constrained Gibbs minimization,*
595 *results in a similar diagram to the unconstrained minimization result for the aluminosilicate*
596 *phase diagram in Figure 3.(ky=kyanite,sill=sillimanite,and=andalusite)* **b)** *Multicomponents*
597 *system phase diagram, with pure phases, using components SiO_2, MgO, H_2O. The same code is*
598 *used as in (a), only the composition and system components need modification (atg =*
599 *antigorite,fo=forsterite,ta=talc,anth=anthophyllite).*

600   Most minerals, fluid and melts are not just pure phases, but can form mixtures of
601 endmembers. The basic example above is shown because essentially the Gibbs minimization
602 approach used in Thermolab is the same for systems in which phases occur that have a variable
603 composition. In the following we shortly outline how we approximate the equilibrium in
604 Thermolab to a reasonable degree by using the same linear programming method.

605   5.1 Linearization of mixtures

606   We compute the Gibbs energy of a set of discrete compositions of the mixture and add
607 them to the list of endmembers as discrete entities, being treated as a fixed composition phase. In
608 the following, all these entities that are the consequence of discretizing a real phase that can form
609 a thermodynamic mixture will be arbitrarily called phase-compounds. With this approach the
610 minimization algorithm remains unchanged from the above case for pure phases in Figure 3c.
611 Figure 5 shows a complete code example to do a calculation with mineral solid solutions using
612 the approach described here.

Figure 5. *Complete example code for the calculation of chemical equilibrium using Gibbs energy minimization including solid solutions, aqueous species and pure phases in Thermolab for the case of serpentinite with addition of carbon (Beinlich et al., 2020). After defining a P and T of interest, the solution model Excel spreadsheet is selected (line 5). The chemical components in the system are defined in line 6 and the composition of the system is specified in line 7. The names of the phases to be considered in the calculation are specified in lines 8-10, where the tc-ds55 identifies the thermodynamic dataset to be used (here THERMOCALC dataset 55). The static thermodynamic data (td) for all phases are loaded in line 11 and stored in one structure array (this replaces the command in Figure 1, line 10). The grid of compositions to linearize the solutions is obtained in line 12. Lines 13-14 compute the density (ZD05 = Z. G. Zhang & Duan, 2005) and dielectric constant of water (S14 = Sverjensky et al., 2014). Line 15 computes the Gibbs energy and volumes of the endmembers in each solution. Line 17 is the call to the main function outlined in Figure 1, and calculates for all phases in the list the Gibbs energy (g), the composition of each phase compound (Npc), an identifier for each phase compound (pc_id. Line 20 performs the constrained Gibbs minimization and in line 22 the data is stored for postprocessing.*

An important step in preparing the mixtures for Gibbs minimization is to generate a grid holding a set of discrete phase compositions representing the mineral, fluid, melt, or gas. The compositions need to cover the full range of possible site fractions or proportions that can exist for a mixture. Fixing the pressure and temperature, Gibbs energy can be calculated either by specifying the site fractions or the proportions. The simplest is to use the site fractions for grid generation because they range from zero to one. Using proportions is more complex because, although proportions sum up to one for each mixture, they can also be negative. Thus, it requires knowledge of the range of values for proportions in each different solution. The grid generation is done in the function call in Line 12, Figure 5, by varying the site fractions by default from 0 to 1, and generating a multi-dimensional cartesian grid over the correct number of independent site fractions, using the MATLAB function "ndgrid" inside. With this brutal way, many non-physical site fractions are generated, but these are removed inside the grid generation function. In summary, we just generate Gibbs energies for the full range of possible site fractions in the

642 solution including all states of ordering and internal speciation. The resulting set of Gibbs
643 energies and compositions is used in place of the example in Figure 3c. The call to the main code
644 'tl_gibbs_energy', in Figure 5 Line 17, now includes the complete Gibbs energy code example
645 Figure 1.

657 As an example of including solutions, we show a variety of phase diagrams, all produced
658 with the same code for a discrete set of P-T values. The first example in Figure 6a, applies the
659 olivine solution model as described above together with a binary melt mixing model, replacing
660 the solid endmembers with their liquid equivalents (liquid forsterite and fayalite). For olivine, a
661 grid is created where z_{Fe}^{M1} and z_{Mg}^{M2} vary independently and for the melt, the site fraction of
662 forsterite liquid is varied. The Margules parameters in the melt are adjusted until they fit the
663 experimental data (Bowen & Schairer, 1935). The T-X diagram including CO_2 fluid using the
664 mixing model of Aranovich and Newton (1999) is produced by changing the bulk CO_2 in the
665 system. When the amount of fluid components (H_2O) in the calculation is orders of magnitude
666 higher than the solid components, the diagram approximates the T-X_{CO2} diagram as the system is
667 largely dominated by fluid. The results show good agreement with the experimental data from
668 Aranovich and Newton (1999). A more complex calculation for a metapelite in KFMASH is
669 done as a benchmark with the Perple_X and THERMOCALC diagrams and shows good
670 agreement, improving the confidence of the method. Note that in complex systems, it becomes
671 increasingly more demanding to get high resolution phase diagrams. For example a computation
672 with the melt model of Holland et al. (2018) yields a low resolution diagram. Additionally,
673 Cr_2O_3, Fe_2O_3 and K_2O were omitted. However, the topology of the diagram is overall similar. In
674 particular, the melt and pyroxene models used in the reproduction of phase diagram for basalt
675 melting is computationally challenging with the method of linearizing the solutions with discrete
676 hypothetical phase compounds.

677 5.2 Postprocessing the minimization results

678 To precompute a lookup table for the local equilibrium the needed unknown variables
679 need to be retrieved from the minimization results. An example is given in Figure 7. The multi-
680 dimensional α array (Line 20, Figure 5) and the corresponding compositions are the only
681 variables that need to be saved along with the P-T arrays.

682 Using the discrete phase compound linearization approach, mixtures (solid solutions,
683 fluids, melts, gas mixtures) are split into individual phases having a fixed composition. The
684 minimization algorithm will determine which of those discrete phases are stable, and for
685 mixtures this often results in multiple discrete phase compounds with different composition of
686 that mixture being stable. This is a mathematical consequence of solving the optimization
687 program and the thermodynamic meaning is that we have a divariant field in which the
688 composition of mixtures may change. Thermodynamically, it can happen that two or three
689 phases are stable as result of a miscibility gap. However, this needs to be determined by an
690 algorithm that distinguishes the discrete phase compound compositions from each other. If they
691 are significantly different for a given resolution of the discretization, then they are true separate
692 phases. In the other case the properties are obtained from a weighted average into one
693 composition for the true stable phase. Afterwards, only the stable phase amount and the
694 composition are retained. A clustering algorithm is used to determine if we have multiple or
695 single phases stable for each particular mixture (Figure 7, line 10).

696   To compute the molar volume of each phase we use the numerical derivative of the Gibbs
697   energy:

```matlab

707   *Line 33-45 calculate the chemical potentials for the components in the phases. From line 56-59*
708   *the results are displayed on the screen as an example.*

709
$$V_{mol} = \left(\frac{\partial G}{\partial P} \right)\Bigg|_T \qquad (44)$$

710   Where the molar mass of each phase is found by:

711
$$\mathbf{m_{mol}} = \mathbf{molm} \cdot \mathbf{N_{phs}} \qquad (45)$$

712   The density of all phases can then be computed:

713
$$\boldsymbol{\rho} = \frac{\mathbf{m_{mol}}}{\mathbf{V_{mol}}} \qquad (46)$$

714   Volume fraction ϕ each phase is then found from molar volume and mole fraction
715   obtained from normalizing α to 1 (e.g. $\varphi_{mol} = \alpha / \sum \alpha$):

716
$$\boldsymbol{\varphi_p} = \frac{\boldsymbol{\varphi_{mol}} \mathbf{V_{mol}}}{\boldsymbol{\varphi_{mol}} \cdot \mathbf{V_{mol}}} \qquad (47)$$

717   And weight fraction of each phase:

718
$$\boldsymbol{\varphi_{wt}} = \frac{\boldsymbol{\varphi_{mol}} \mathbf{m_{mol}}}{\boldsymbol{\varphi_{mol}} \cdot \mathbf{m_{mol}}} \qquad (48)$$

719   Composition in weight is found from:

720
$$\mathbf{C_{wt}} = \frac{\mathbf{N_{phs} molm}}{\mathbf{N_{phs}} \cdot \mathbf{molm}} \qquad (49)$$

721   Properties for total rock and fluid can be found from

722
$$\rho_s = \boldsymbol{\rho_{ss}} \cdot \boldsymbol{\varphi_{ss}} \qquad (50)$$

723   Where the vectors hold the densities of all solid minerals including both pure phases and
724   solid solutions, and their volume fractions. Fluid density is simply the density of the fluid
725   mixture from equation and needs no further processing. Total solid concentrations are obtained
726   from summing for each component the weight of all solids and dividing over the total weight.

727   Chemical potential is calculated following:

728
$$\mu_i = \mu_{np} + \frac{\partial g}{\partial p_i}$$
(51)

729   Where μ_{np} is the chemical potential of the last dependent proportions (as proportions sum
730   up to 1) and is calculated from:

731
$$\mu_{np} = g - \sum_{i=1}^{np-1} p_i \frac{\partial g}{\partial p_i}$$
(52)

732   5.3 Improving the calculations

733   Increasing the resolution of the P-T grid improves the smoothness of the lines in the
734   diagram, but it does not ultimately lead to a better calculation. This is illustrated in Figure 8,
735   where the resolution of the T-X grid for the olivine diagram is kept constant, while the number of
736   discrete compositions for which the olivine and melt are calculated is increased. This means that
737   the mixture is better approximated, and the result is that the compositions and modal abundances
738   become better resolved and the step-like behavior that is present in the calculation with lower
739   compositional grid gradually disappears. Although this is feasible for calculations that involve
740   one or two simple mixtures, like binary olivine and melt, the computational demand required for
741   more complex chemical systems and minerals makes such high-resolution compositional grids
742   unpractical for computation. Even if computers with abundant memory are employed, we found
743   that linprog will not find a solution for systems with more than 2 million discrete phases in the
744   minimization.

745   Another option to improve the calculation is therefore to refine compositions in an
746   iterative approach as also suggested and employed since decades (Connolly, 2009; Rossi et al.,
747   2009; W. B. White et al., 1958). In Thermolab, this is open for the user to implement or improve.
748   Here we describe a simple approach that currently is employed as a working example. First, an
749   initial minimization is done with a suitable compositional starting grid. This initial starting grid
750   is also subject to possible modification and improvement; however, it is possible to simply set up
751   a coarse resolution initial grid so that each minimization is fast. Each discrete phase which has an
752   alpha above zero is recognized as a stable phase. And the index in the list of non-zero alpha is
753   used to find the composition of the mixture in terms of the endmember proportions and site
754   fractions. In the next step, the proportions are used to generate a denser (i.e., higher resolution)
755   compositional grid around the stable proportions found in the first minimization. For a binary, a
756   simple graphical explanation of this procedure in Thermolab is illustrated in Figure 9. The new
757   higher resolution compositional grid is added to the already existing grid and taken to the next
758   iteration. We checked that the Gibbs energy of the system is always decreasing during the
759   iterations. The iterations are stopped when the Gibbs energy of the system is not changing
760   anymore within limits of machine-precision, or when the compositional spacing in the refined

761   grid reaches this tolerance. This leads to improved calculation of compositions, modal

762   abundances, as shown in Figure 10 for the metapelite (KFMASH) P-T diagram from Figure 6c.
Figure 8 *Influence of resolution of the discretization of solutions on the quality of the thermodynamic calculations. T-X resolution is kept constant at 300x300 steps. By increasing the number of compounds to discretize the mixtures, melt and olivine, the quality of the data is improved and the stepwise behaviour disappears. The melt and olivine binary mixing curves are approximated with 15, 50 and 100 discrete compounds (n). **a)** Fraction of melt with the melt and solid discretized with 15 compounds. **b)** Melt composition (X_{fo}) corresponding to (a). **c)** As in (a), for n = 50 compounds. **d)** Melt composition corresponding to (c). **e)** As in (a) with n = 100 compounds. **f)** Melt composition corresponding to (e). **g,h)** One-dimensional profiles for melt fraction and composition at X_{sys}=0.5, (dashed lines in a-f). Improvement of calculation with higher number of compounds clearly visible by smoothening of the lines as resolution increases.*
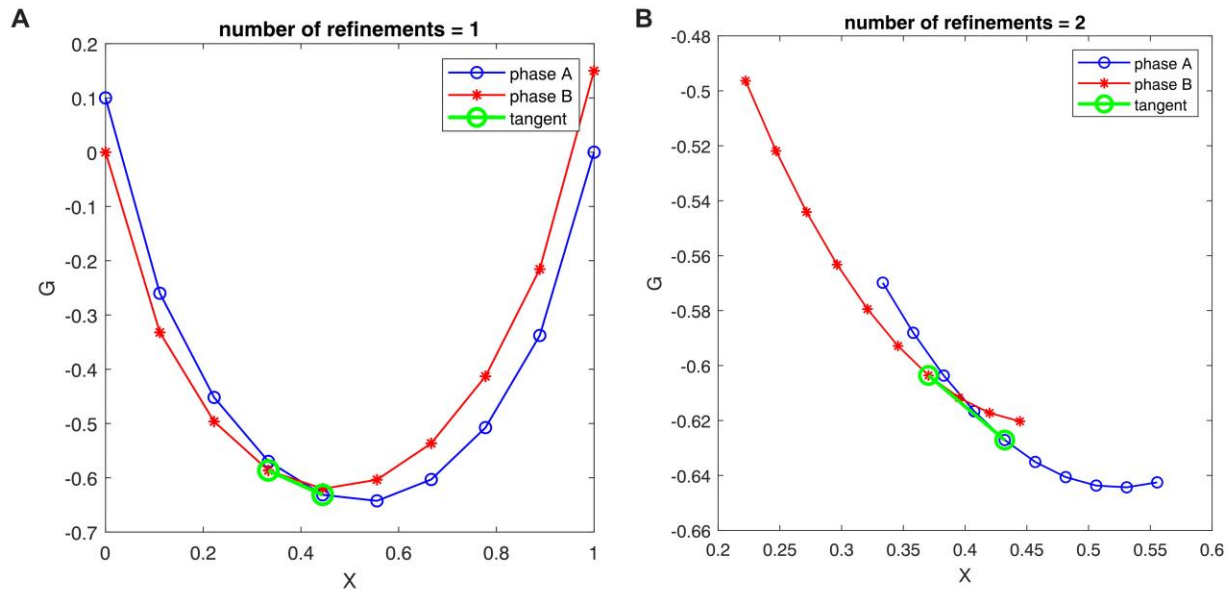

Figure 9. *Conceptual diagrams showing two steps in the refinement of the composition of mixtures. **a)** Shows an initial minimization result which is then zoomed in and refined around the solution in step one. **b)** Here the refined compositions are used for a second minimization with smaller compositional spacing between the discretized mixture, without increasing the number of discrete compounds, thereby avoiding using too much computer memory.*

6 Investigating non-linear transport processes in open systems

Coupling local equilibrium thermodynamics to transport processes such as the system of equations introduced above has been discussed previously (e.g. Malvoisin et al., 2015). The method described here follows the approach employed in recent studies of Malvoisin et al, 2015, Plümper et al, 2017, Beinlich et al. 2020). For the transport models a complete set of equilibria for all possible external conditions, T, P, X, may be pre-computed and stored in a lookup table. To this end, loops over P, T, and X can be programmed around the linprog minimization and stored in a database. As an example, we show the soapstone formation in serpentinite from Beinlich et al. (2020). To the initial bulk serpentinite composition carbon (C) is added to produce a lookup table of 150 different bulk compositions at fixed T, and P. Employing the refinement method above, the Beinlich et al (2020), thermodynamic calculations can be improved in smoothness and computation speed (Figure 12b,d,f). However, the main results are the same.

790   The important aspect is that the Beinlich et al. (2020) calculation was more robust, because no
791   iterative refinement was used and hence any chance of reaching a local-minimum rather than the
792   true minimum was avoided. Thus, the results of Beinlich et al. (2020) serve as benchmark for the
793   refinement algorithm described above.
794   **Figure 10.** *Example of a phase diagram after refinement. The mineral modes in **a)-e)** show*
795   *smooth variations within the phase fields due to sufficiently resolving the compositions of*

796 *mixtures in a iterative refinement procedure. The final phase diagram in f) shows also*
797 *improvement, but the general topology was also captured in Figure 6c.*

798 6.1 Reactive transport example

799 After retrieving the density of solid, fluid, and concentration of fluid and solid, and the
800 chemical potential, the system of equations described above can be solved. Here a possible
801 numerical implementation in MATLAB is shown, using explicit finite differences. The purpose
802 is to focus on the concept of coupling the transport processes to the precomputed local
803 equilibrium lookup table and to show the effect of the non-ideal solution models on reactive
804 transport.

805 As stated above, there are three equations and 8 unknowns. The first equation is the
806 rearranged total mass balance equation in which the only assumption is that solid is not
807 deforming. The fluid velocities have been substituted by the Darcy flux. This equation is used to
808 find the unknown fluid pressure. The second equation is a mass concentration balance of an
809 immobile component in the solid. This equation can be integrated analytically in case of non-
810 deforming solid and used to calculate the unknown porosity (e. g. Appendix Malvoisin et al.
811 2015). The last equation is the total mass concentration balance for a component that is mobile,
812 (in Beinlich et al. 2020 this is carbon). From this equation the total mass concentration is found
813 which subsequently can be used to find the solid concentration.

814 Equation (1) can be written as:

$$\frac{\partial \rho_{tot}}{\partial t} = -\nabla \cdot \left(\rho_f q_D \right) \tag{53}$$

816 With:

$$\rho_{tot} = \rho_f \phi + \rho_s \left(1 - \phi \right) \tag{54}$$

818 and (Figure 11, Line 49):

$$q_D = -\frac{k^0 \phi^3}{\mu_f} \nabla P_f \tag{55}$$

820 When assuming a relation between total density and fluid pressure using an effective
821 compressibility, we can write the above (Figure 11, line 55):

$$\beta_e \frac{\partial P_f}{\partial t} = -\nabla \cdot \left(\rho_f q_D \right) \tag{56}$$

823 And with the porosity equation (Figure 11, Line 56):

$$\varphi_f = 1 - \frac{\left(1 - \varphi_{f_0} \right) \rho_{s_0} C_{s_0}^{Mg}}{\rho_s C_s^{Mg}} \tag{57}$$

825   using the concentration of magnesium in solid as immobile species and specifying the
826 initial density, porosity and concentration. Total concentration of mobile species carbon, is
827 solved by rearranging the total mass concentration balance (Figure 11, Line 57):

828
$$\frac{\partial c_{sys}}{\partial t} = \nabla \bullet \left(\rho_f C_f \varphi D_{C_f} \nabla \mu + \rho_f C_f q_D \right) \tag{58}$$

830   *precomputed thermodynamic equilibrium data (line 3), the physical parameters are defined in*
831   *lines 8-19, the numerical parameters (e.g. number of time steps and nodes in the model) are*
832   *defined (lines 21-23). Preprocessing and initialization including setup of the grid and initial*
833   *conditions are done in lines 28-33. Here an incoming fluid and fluid pressure increase is setup*
834   *as left boundary to initialize reactive fluid flow from left to right. In lines 36-40 all properties*
835   *retrieved from local equilibrium are found by interpolating on the precomputed thermodynamic*
836   *equilibrium data. Line 41 stores the initial condition for the non-mobile solid and the initial*
837   *porosity distribution is set to a constant value (phi0 in line 12). Line 43 is the definition of total*
838   *concentration in the system (Eq.* (59)*). Averaging values used in fluxes defined between the*
839   *nodes are calculated in line 44-46. Lines 48-49 are the driving forces for the reactive transport,*
840   *flux of diffusion (qC) and Darcy flux Eq.* (55)*. Adaptive time steps, approximately following*
841   *Courant Friedrichs-Lewy stability criterium, are calculated in lines 51-53 to constrain*
842   *numerical error propagation and maintain stability of the numerics. Line 55-57 are most*
843   *fundamental governing physics in the reactive transport, the main equations* (1), (2), *and* (3), *by*
844   *reformulating it to the equations* (56), (57), *and* (58). *The solid concentration is found from the*
845   *definition of total system mass concentration* (59)*). Plotting takes place during model run every*
846   *'nout' time steps. The phase abundances can be visualized when desired as they are interpolated*
847   *from the lookup table and do not enter any of the physics equations. Plotting of the*
848   *mineralogical evolution is done in lines 61-63.*

849

850   With (Figure 11, Line 43):

851
$$c_{sys} = \rho_f C_f \varphi_f + \rho_s C_s \left(1 - \varphi_f\right) \tag{59}$$

852   Then solid concentration is found by rearranging the above (Figure 11, Line 58):

853
$$C_s = \frac{c_{sys} - \rho_f C_f \varphi_f}{\rho_s \left(1 - \varphi_f\right)} \tag{60}$$

854   The remaining unknowns, ρ_f, ρ_s ,C_{sMg}, and C_f are found from interpolation in the lookup
855 table at each time step (Figure 11, Line 36-40). Details of the coding example are found in the
856 caption of Figure 11 and results of the transport code are shown in Figure 12. The non-linearity
857 of the thermodynamic relationship between solid and fluid composition is demonstrated in
858 Figure (12,c,d,f), this is a result of both the non-ideality of solution models as well as changes in
859 the phase assemblage. Depending on the function of solid composition versus fluid composition,
860 the reaction fronts behave very differently in terms of shape and velocity (Figure 12, a, c,e).

861   6.2 Cahn-Hilliard exsolution

862 Natural processes usually are not in equilibrium and do not strictly follow the path that can be
863 followed from a phase diagram. Instead, there will be a process that develops towards the state of
864 global equilibrium depicted on a phase diagram although it may never reach it (e.g. due to
865 thermal closure). With Thermolab, the Gibbs energies can be directly used instead of first
866 calculating thermodynamic equilibrium and the process towards equilibrium can be modelled. A
867 demonstration of this is given by solving the Cahn-Hilliard equations in which driving force for
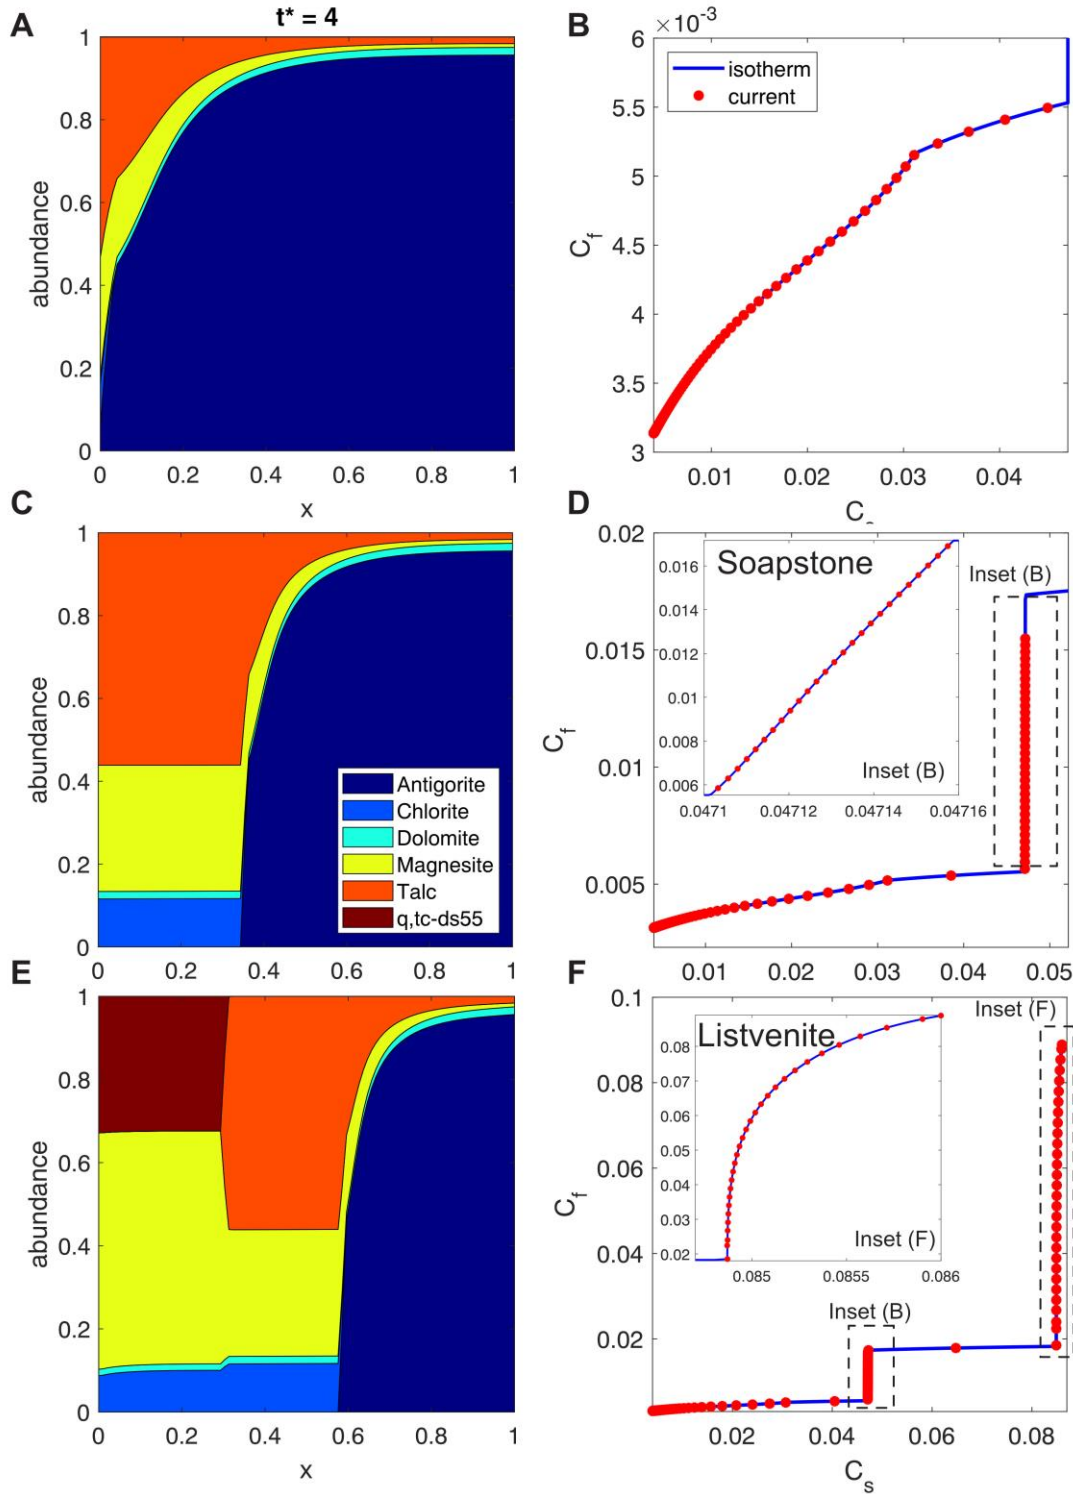

Figure 12. *Snapshot of reaction fronts produced by influx of three different incoming CO₂ fluid compositions from the left boundary into a serpentinite using the code in Figure 11. For comparison all runs were stopped after the same duration. In all cases, the starting rock consists primarily of serpentine (here antigorite), with minor amounts of talc, magnesite and dolomite. **a)** If the incoming fluid composition lies below ~0.005 antigorite never completely disappears and a*

873   *gradual reaction front forms transforming the serpentinite to ophimagnesite (magnesite-talc-*
874   *serpentinite). **b**) The equilibrium relation between C_f and C_s (i.e. the isotherm) shown in blue*
875   *with the transient (current) C_f and C_s compositions plotted as red dots. **c**) With an incoming fluid*
876   *composition between 0.01-0.015, the pristine serpentinite to the right transforms into soapstone*
877   *with a sharp reaction front when antigorite has reacted out. **d**) The equilibrium relation between*
878   *C_f and C_s (i.e. the isotherm). The steep slope at C_s between ~0.045-0.052 is enlarged in the inset.*
879   *Here antigorite disappears (the soapstone on the left in Figure c), and the steepness of the slope*
880   *on the isotherm causes a sharp soapstone front. The shallow slopes below $C_s=0.045$ correspond*
881   *to the transitional front where serpenitinite is partially transformed to soapstone. **e**)*
882   *Development of an additional reaction front, forming listvenite (quartz-magnesite rock), as*
883   *incoming fluid composition is now higher, ~ 0.086 weight fraction dissolved carbon. **f**) As the*
884   *incoming fluid composition lies on anorther steep part of the isotherm, the listvenite front is also*
885   *sharp. Inset shows the curvature of the isotherm corresponding to the listvenite stable*
886   *assemblage. Endmember data from the tc-ds55 dataset (Holland & Powell, 1998), solution*

888   *Chlorite (Holland et al., 1998), Talc (Holland & Powell, 1998), Magnesite, Dolomite (R. W.*
889   *White et al., 2003). t* = dimensionless time. Concentration units are in elemental carbon weight*
890   *fraction.*

891   diffusion is chemical potential and an uphill diffusion process causes an initial random
892   homogeneous system to develop into an equilibrium phase assemblage (Cahn & Hilliard, 1958).
893   A simplified version of the Cahn-Hilliard equation consists of a balance of mass concentration
894   and a flux equation for the diffusion. Assuming a system without fluid, and assuming constant
895   densities a basic mass concentration balance can be written (Figure 13, line 35):

896
$$\frac{\partial C_{s,1}}{\partial t} = -\frac{\partial q_{c_{s,1}}}{\partial x} \tag{61}$$

897   Flux of concentration in solid of a component can be defined as a function of gradients in
898   chemical potential differences or a single chemical potential in conjuction with the Gibbs-Duhem
899   relation (e.g. p. 80 in Lebon et al., 2008; Nauman & He, 2001), here the former is used (Figure
900   13, line 34):

901
$$q_{c_{s,1}} = -D_{c_{s,1}} C_{s,1} \frac{\partial \left(\mu_{C_{s,1}} - \mu_{C_{s,2}} \right)}{\partial x} \tag{62}$$

902   The chemical potential difference can be conveniently expressed by:

903
$$\mu_{C_{s,1}} - \mu_{C_{s,2}} = \frac{\partial g_{mix}}{\partial C_{s,1}} - \gamma \frac{\partial^2 C_{s,1}}{\partial x^2} \tag{63}$$

904   where the last term in (63) is the interfacial free energy contribution as introduced by
905   Cahn-Hilliard (1958). Similar to Figure 7, the chemical potential can be calculated with
906   numerical differentiation of the Gibbs energy (see Figure 13, line 31-32).

907   These equations describe the spinodal decomposition of a phase with strong non-ideal
908 behaviour, such as feldspar, due to non-linear diffusion driven by chemical potential gradients. A
909 useful review is found in Nauman & He (2001). See also caption Figure 14 for details.

Binary 1-D

Ternary 2-D
Figure 14 *Example of using Thermolab without precomputed thermodynamic data. Physical processes develop towards thermodynamic equilibrium using the Cahn-Hilliard model at 500 °C, 0.1 GPa. The 1D example code for a binary system is given in Figure 13. An initially homogenous concentration distribution in a single phase develops into a two phase system due to uphill diffusion as a result of the non-linearity of solution models (the non-ideality that leads to exsolution of phases). **a)** Snapshot of a 1D model during exsolution of binary feldspar (concentration corresponds to albite component in albite-sanidine mixture). Red line shows initial concentration distribution developing into separate phases represented by the blue line. **b)** Comparing the concentrations in the physical domain to the Gibbs energy-composition (X) curve (for clarity only the mixing energy, ideal + non-ideal is shown). Plotting the transient concentrations on the equilibrium curve shows that the system develops towards the tangent construction (i.e. equilibrium condition) shown with the yellow line and calculated with 'linprog' following methods described in the main text. **c)** Albite concentration in a 2D feldspar model after exsolving for some time from a homogeneous initial distribution. **d)**, and **e)** represent the corresponding compositions of respectively, components anorthite, orthoclase (using sanidine endmember here). **f)** transient compositions of the feldspar for all nodes in the 2D domain plotted on the equilibrium mixing Gibbs-energy ternary represented by the contours. These compositions form a continuous yellow line (as there are many overlapping symbols). Dashed line corresponds to solvus computed with 'linprog', and yellow open circle corresponds to average concentration in the system. Red symbols are equilibrium compositions of the two stable phases from Gibbs minimization.*

7 Discussion

The motivation befind the development of Thermolab is to study the effects of the non-ideality of solution models in reactive transport processes in open systems. Most natural materials including minerals, rocks, melt, fluids and gases display some degree of non-ideal mixing behaviour (e.g. Ganguly, 2020). We showed that for the case study of the soapstone formation studied by Beinlich et al. (2020) both the shape and the velocity of the reaction front vary strongly depending on the non-linearity of the partitioning of carbon between fluid and solid (Figure 12). For evaluating potential risks during transport of nuclear waste material understanding this non-linear behaviour is crucial and a study of Shao et al. (2009) is line with this conclusion.

For mathematical analysis the formulation of complex solution models is important to show in a transparent manner such that non-linearities in transport processes can be studied. Therefore we presented the linear algebraic approach that is used in Thermolab to compute Gibbs energy of mixing for arbitrary multi-component phases (Figure 1). The starting point was a crystallographic or structural model of a solution and a predefined set of endmembers as developed by previous workers (e.g. Green et al., 2016; Palin et al., 2016). More in depth discussion on how to newly define crystallographic and speciation models for solid solutions is given by Myhill & Connolly (2021), after which the model should then be fitted to experimental data.

Complex solution models are almost exclusively used for phase diagram calculations (e.g. Connolly, 2005, 2009; de Capitani & Brown, 1987; Ghiorso et al., 2002; Holland & Powell, 1998, 2011; Johnson et al., 1992), but usually not for the transport codes. To ensure the reliability of the Gibbs energy calculation and equilibrium calculation methods, Thermolab is

971   benchmarked versus phase diagrams and exemplified in use for reactive transport projects.
972   Constrained Gibbs energy minimization is discussed following existing approaches (Connolly,
973   2005; W. B. White et al., 1958) and the results are then used to calculate equilibrium
974   compositions and retrieve the so-called isotherm that can be used in a transport code.

975   The isotherm, introduced in chromatographic studies of metasomatism, is a relation
976   between fluid and solid composition at fixed P-T (Hofmann, 1972). An approach in which the
977   system is divided in solid and fluid and for which the mass conservations equations have been
978   summed up to eliminate reaction source terms has proven very useful for reaction front
979   propagation studies (Orr, 2005). Shape and velocity of propagating reaction fronts strongly
980   depend on the non-linearity of solutions models (Guy, 1993). The approach of pre-computing the
981   equilibrium compositions and using the results as an isotherm in the transport codes is useful to
982   study the effects of the non-linearity of solution models on reactive transport. As the studies of
983   Hofmann (1972) and Guy (1993) focus on single phases, our results shows this is functioning
984   similarly on multi-phase systems such as rocks. The steep reaction fronts act similar to isotherms
985   with miscibility gaps (Fletcher & Hofmann, 1974), but the solid solutions are responsible for the
986   continuity of the isotherm across the 'jump-like' curves. Previous studies usually introduced
987   simple isotherms, also called flow functions, to study the behaviour during transport. Thermolab
988   has been motivated by the need to generate realistic flow functions using complex solution
989   models.

990   Solid solutions with strong non-ideal behaviour result in phase separation due to non-
991   linear diffusion when combined with transport models. The Cahn-Hilliard model (Cahn &
992   Hilliard, 1958) is used to stabilize the numerical solutions by introducing an energy penalty for
993   generating surfaces between phases introduced by a surface energy parameter. This method is
994   widely applied in material science (Nauman & He, 2001) and also some geological appliciations
995   have been studied (Abart et al., 2009; Petrishcheva & Abart, 2009). For geological materials
996   other than feldspar, the behaviour of such non-linear diffusion systems can be further
997   investigated with Thermolab.

998   Mixing of databases is possible in a flexible framework like Thermolab, however it may
999   not be recommended since internally consistent databases are not necessarily consistent amongst
1000   each other. Nevertheless, to use aqueous species in fluids together with most up to date solution
1001   models of minerals, the only possibility to date is to combine for example SUPCRT databases
1002   with Holland and Powell (1998, 2011). It has been argued that such a combination may serve as
1003   a good approximation (Dolejš, 2013), when appropriate equations of state and dielectric constant
1004   for water are used. However, refitting the aqueous species databases from SUPCRT in
1005   conjunction with mineral database of Holland and Powell (1998) is likely the more reliable
1006   approach to combine datasets (Miron et al., 2016; Miron et al., 2017).

8 Conclusions

1008   With thermolab it is possible to reproduce published phase diagrams involving complex
1009   solution models and these solution models can then be used in transport codes to investigate the
1010   effects of non-linearity on the open system processes. Complex flow functions can be retrieved
1011   from Thermolab and used in mathematical analysis and numerical models of reactive transport.
1012   Gibbs energy can be directly used to construct chemical potentials as driving force for non-linear
1013   diffions leading to phase separation.

1014   The modelling framework provided by Thermolab allows users to add custom functions,
1015 include new databases, design solution models but also improve procedures to calculate
1016 equilibrium. Limits of the discretization of solutions approach are due to computer memory
1017 restrictions, which for complex solution models increases computation time to unpractical
1018 durations. Computers with increased memory would be a solution, however, we found that the
1019 linprog algorithm will stop to converge when about 2 million discrete phases or more in systems
1020 with more than six components are used. Refinement strategies are a potential solution to this
1021 problem; however, these compromise the robustness of the result by possibly missing the global
1022 minimum of the Gibbs energy. Thus, Thermolab leaves the door open for development of faster
1023 and more robust future algorithms by a transparent open source coding environment, which due
1024 to the compactness of MATLAB example code can be translated to other programming
1025 languages with minimum effort.
