## Abstract

The Ethiopia-Yemen flood basalts are spatially zoned with progressively lower TiO<sub>2</sub> lavas from near the Afar depression toward the margins. The timing and rate of emplacement of low TiO<sub>2</sub> (LT) lavas are poorly known compared with the ultra-high TiO<sub>2</sub> (HT2) lavas. We measured two high-precision <sup>40</sup>Ar/<sup>39</sup>Ar ages of  $29.63 \pm 0.14$  and  $30.02 \pm 0.22$  Ma ( $2\sigma$ ) from basalts of the 2-km-thick LT lava sequence at the Afar plume head margin. Using our eruption age model constructed from our and previous <sup>40</sup>Ar/<sup>39</sup>Ar ages with the paleomagnetic directions, we estimate that the LT lava eruption continued over Chrons C12r-C12n-C11r. The eruption of the plume head margin started earlier than the plume head axis emplacement in C12n. Also, the eruption rate was low at the margin, high at the axis. We estimate that the LT lavas are induced by the edge-driven convection, the result of a plume-lithosphere interaction, not a plume head.

## 18 Key Points:

- We obtain two new  $^{40}\text{Ar}/^{39}\text{Ar}$  ages for the low-Ti basalt from the Lima-Limo section of the Ethiopia–Yemen flood basalts
  - Based on our eruptive age model, we correlate the Lima-Limo section to Chrons C12r to C11r
  - We conclude that the non-plume low-Ti basalts erupted before the Afar plume high-Ti basalts because of the plume–lithosphere interaction

**26 Abstract**

27 The Ethiopia-Yemen flood basalts are spatially zoned with progressively lower TiO<sub>2</sub> lavas from  
28 near the Afar depression toward the margins. The timing and rate of emplacement of low TiO<sub>2</sub>  
29 (LT) lavas are poorly known compared with the ultra-high TiO<sub>2</sub> (HT2) lavas. We measured two  
30 high-precision <sup>40</sup>Ar/<sup>39</sup>Ar ages of 29.63 ± 0.14 and 30.02 ± 0.22 Ma (2σ) from basalts of the 2-km-  
31 thick LT lava sequence at the Afar plume head margin. Using our eruption age model constructed  
32 from our and previous <sup>40</sup>Ar/<sup>39</sup>Ar ages with the paleomagnetic directions, we estimate that the LT  
33 lava eruption continued over Chrons C12r-C12n-C11r. The eruption of the plume head margin  
34 started earlier than the plume head axis emplacement in C12n. Also, the eruption rate was low at  
35 the margin, high at the axis. We estimate that the LT lavas are induced by the edge-driven  
36 convection, the result of a plume-lithosphere interaction, not a plume head.

37

**38 Plain Language Summary**

39 The Ethiopia-Yemen Flood Basalts are the expression of a mantle plume erupting millions of km<sup>3</sup>  
40 of basaltic lava in a geologically short period (1-3 million years (Myr)). Titanium concentrations  
41 in the flood basalts are zoned and named HT2, HT1, and LT basalts (from high to low Ti). The  
42 eruption timing and rate of the HT2 basalts are constrained with high precision, but those of the  
43 LT basalts remain ambiguous. Therefore, we measured two high-precision <sup>40</sup>Ar/<sup>39</sup>Ar ages from LT  
44 basalts in the 2-km-thick Lima-Limo section, which erupted northwest of the Afar area. Based on  
45 our eruption age model constructed from <sup>40</sup>Ar/<sup>39</sup>Ar ages and paleomagnetic directions, we estimate  
46 that the eruption of the LT basalts started earlier than the HT2 basalts that erupted in Chron C12n  
47 and lasted over at most ~2 Myr. The eruptive rate of the LT basalts (0.02-4.69 km<sup>3</sup>/yr) in the  
48 earliest interval was lower than that of the HT2 basalts (4-13 km<sup>3</sup>/yr). We may explain that this  
49 eruption feature by a thickness gradient in the lithosphere on the Afar mantle plume at that time.

50

**51 1 Introduction**

52 Understanding of the flood basalt eruptions is essential because it provides clues to past  
53 mantle plume activity. The Afar Plume formed the Afro-Arabian Large Igneous Province  
54 (AALIP) over three periods, the Eocene, Oligocene, and Miocene (Rooney, 2017), and is one of  
55 the freshest flood basalts on Earth. The most active emplacement of AALIP occurred in the  
56 Oligocene (e.g., Hofmann et al., 1997), called the Oligocene Ethiopian-Yemen Traps, and  
57 geochemical studies of the Oligocene flood basalts have clarified that basalts show zoning with Ti  
58 content (Pik et al., 1998). Low Ti tholeiitic lavas (LT, TiO<sub>2</sub>: 1–3 wt%) occur in the western part,  
59 high Ti tholeiitic lavas (HT1, TiO<sub>2</sub>: 2–4 wt%) in the eastern part, and ultra-high Ti transitional  
60 basalt/picrite lavas (HT2, TiO<sub>2</sub> 3–7 wt %) near the Afar triple junction (Fig. 1a) (Pik et al., 1998;  
61 Beccaluva et al., 2009; Natali et al., 2016; Rooney, 2017). HT2 lava has a high mantle potential  
62 temperature (Beccaluva et al., 2009; Natali et al., 2016). Since high <sup>4</sup>He/<sup>3</sup>He ratios were reported  
63 from HT2 lava, it is thought to be of deep mantle origin, consistent with the plume hypothesis  
64 (Marty et al., 1996; Natali et al., 2016). Mantle seismic tomography also suggests that the Afar  
65 plume rises from the bottom of the lower mantle (French and Romanowicz, 2015; Boyce et al.,  
66 2021). The HT2 basalts are the earliest eruptions of the Oligocene Ethiopia-Yemen Traps and are  
67 estimated to have significantly high emplacement rates (Eid et al., 2021). However, the timing and

68 rate of the emplacement of LT lavas have not been uniquely determined, and their eruption rates  
 69 remain ambiguous (Fig. 1b) (Ahn et al., 2021; Eid et al., 2021).

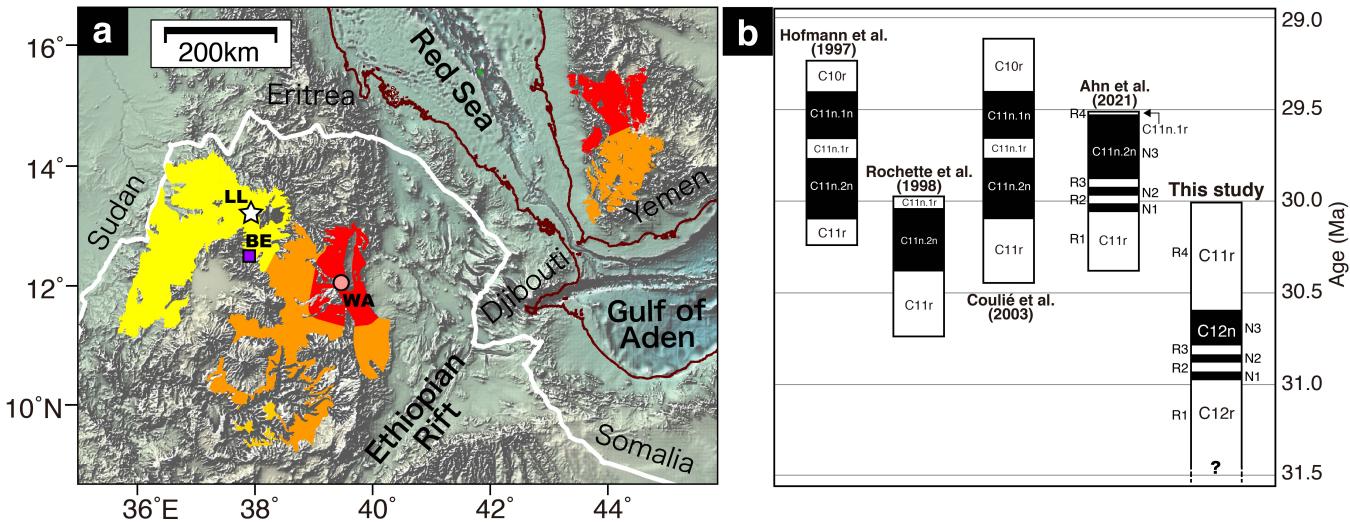

70 The Oligocene Ethiopia–Yemen Traps are one of the three volcanic pulses of AALIP from  
 71 the Eocene to the Miocene (Rooney, 2017). In the Lima-Limo section of the Traps, one of the  
 72 thickest LT basalt sections in northwestern Ethiopia (Fig. 1a), several studies on paleomagnetism  
 73 and  $^{40}\text{Ar}/^{39}\text{Ar}$  age estimated that its eruption duration is 0.8–1.5 million years or less (Myr)  
 74 (Hofmann et al., 1997; Rochette et al., 1998; Coulié et al., 2003; Ahn et al., 2021). Hofmann et al.  
 75 (1997) and Rochette et al. (1998) conducted a magnetostratigraphic and  $^{40}\text{Ar}/^{39}\text{Ar}$  study of the  
 76 Lima-Limo section of the Traps and interpreted that the main part of the Traps erupted at about 30  
 77 Ma in a short period of time, less than 1.5 Myr. They identified a R–N–R polarity sequence and  
 78 correlated it with Chrons C11r–C11n or C11r–C10r in the Geomagnetic Polarity Time Scale  
 79 (GPTS) of Heustis and Acton (1997) (Fig. 1b). Coulié et al. (2003) performed K/Ar and  $^{40}\text{Ar}/^{39}\text{Ar}$   
 80 datings and improved the correlation of the magnetostratigraphy of Rochette et al. (1998) with  
 81 GPTS of Cande and Kent (1995) (Fig. 1b). However, previous studies couldn't establish a unique  
 82 magnetostratigraphic correlation with GPTS (Fig. 1b). Recently, seven magnetozones were  
 83 identified from the Traps: R1–N1–R2–N2–R3–N3–R4, from the bottom to the top of the section  
 84 (Ahn et al., 2021). These newly found magnetozones make unique correlations to GPTS more  
 85 difficult. The reason for the lack of the unique magnetostratigraphic correlation of the Lima-Limo  
 86 section in previous studies is that they did not construct any eruption age models using the  
 87  $^{40}\text{Ar}/^{39}\text{Ar}$  ages, which should be based on a common standard age. Furthermore, it is necessary to  
 88 use as many  $^{40}\text{Ar}/^{39}\text{Ar}$  ages as possible in order to construct high-precision age models. Therefore,  
 89 in this paper, we report new high-precision  $^{40}\text{Ar}/^{39}\text{Ar}$  ages of lavas from the Lima-Limo section  
 90 and combine them with previously reported  $^{40}\text{Ar}/^{39}\text{Ar}$  ages and construct an age model to estimate  
 91 the eruption timing and rate.

## 92 2 Geological Setting, Samples and Methods

### 93 2.1 Geological Setting

94 The Oligocene Ethiopia–Yemen Traps in the Lima-Limo section erupted at ~30 Ma  
 95 (Hofmann et al., 1997; Rochette et al., 1998; Coulié et al., 2003), which was before the Afro-  
 96 Arabian continental breakup (Bosworth et al., 2005). Continuous lava piles that erupted at ~30 Ma  
 97 have also been found in other areas of Ethiopia (e.g., Prave et al., 2016; Lhuillier and Gilder, 2019;  
 98 Eid et al., 2021). After the continental breakup, the Traps split into two parts, 90% in Ethiopia and  
 99 10% in the Arabian Peninsula (Fig. 1a). Currently, the area of the main part of the Traps in Ethiopia  
 100 is ~600,000 km<sup>2</sup> (Mohr, 1983). The total lava thickness of the Lima-Limo section reaches ~2 km,  
 101 and all lava flows are LT basalts. The total volume of the Oligocene Ethiopia–Yemen Traps is  
 102 estimated to be 350000 km<sup>3</sup> (Mohr, 1983; Mohr and Zanettin, 1988). The lower part (<~2200 m)  
 103 is characterized by thin lava flows (<10 m) and a gentle slope morphology. In contrast, the upper  
 104 part (>~2200 m) consists mainly of thick lava flows (10–100 m), forming cliffs with clear breaks  
 105 along flow contacts (Ahn et al., 2021). In the Oligocene Ethiopia–Yemen Traps consisting of a  
 106 large range of compositions from low-Ti to high-Ti basalts, in particular, the eruption rate of HT2

107 basalt in the Waja section may have been higher than that of LT basalt in the Belessa and Lima-  
108 Limo sections (Eid et al., 2021).

109 **Figure 1.** (a) Schematic map of the Oligocene Ethiopia–Yemen Traps (after Rooney, 2017).  
110 Section names are: Lima-Limo (LL, this study), Belessa (BE), and Waja (WA). Yellow, orange,  
111 and red colors show the spatial distribution of the basalt lavas of different titanium  
112 concentrations (Pik et al., 1998): LT,  $\text{TiO}_2$  1–3 wt%, HT1,  $\text{TiO}_2$  2–4 wt%, and HT2,  $\text{TiO}_2$  3–7  
113 wt%. The thick white line indicate the Ethiopian border. (b) Summary of previous and our  
114 magnetostratigraphic correlations of the Lima-Limo section. The reference GPTS are Cande and  
115 Kent (1995) for Hofmann et al. (1997), Huestis and Acton (1997) for Rochette et al. (1998),  
116 Cande and Kent (1995) for Coulié et al. (2003), Ogg et al. (2016) for Ahn et al. (2021), and Ogg  
117 (2020) for this study. When alternative age correlations were proposed in the previous studies,  
118 only the correlations preferred by the original authors in each study are presented here. We label  
119 the geomagnetic reversals in Chron C12n as the ‘Lima-Limo reversals’ and assumed that the  
120 Lima-Limo reversals are evenly distributed over the early half of Chron C12n.

## 121 2.2 Samples

122 We used the same LT lava samples as those in previous paleomagnetic studies (Fig. 1a,  
123 S1) (Yoshimura et al., 2020; Ahn et al., 2021). Before the dating experiments, we selected samples  
124 by inspecting thin sections to avoid contamination from secondary minerals. Photographs of the  
125 thin sections are shown in Fig. S2. Samples A1–61 and A2–162 are from two reversely magnetized  
126 lava flows belonging to the R4 magnetozone. Samples A2–482 and A2–604 are from the normally  
127 magnetized lava flows of the N3 and N1 magnetozones, respectively.

## 128 2.3 $^{40}\text{Ar}/^{39}\text{Ar}$ dating

129 We determined the ages of the basalt samples from the Lima-Limo section using the  
130  $^{40}\text{Ar}/^{39}\text{Ar}$  dating instrument at the Geological Survey of Japan, AIST. The details of the procedures  
131 are described in Ishizuka et al. (2018) and Text S1.

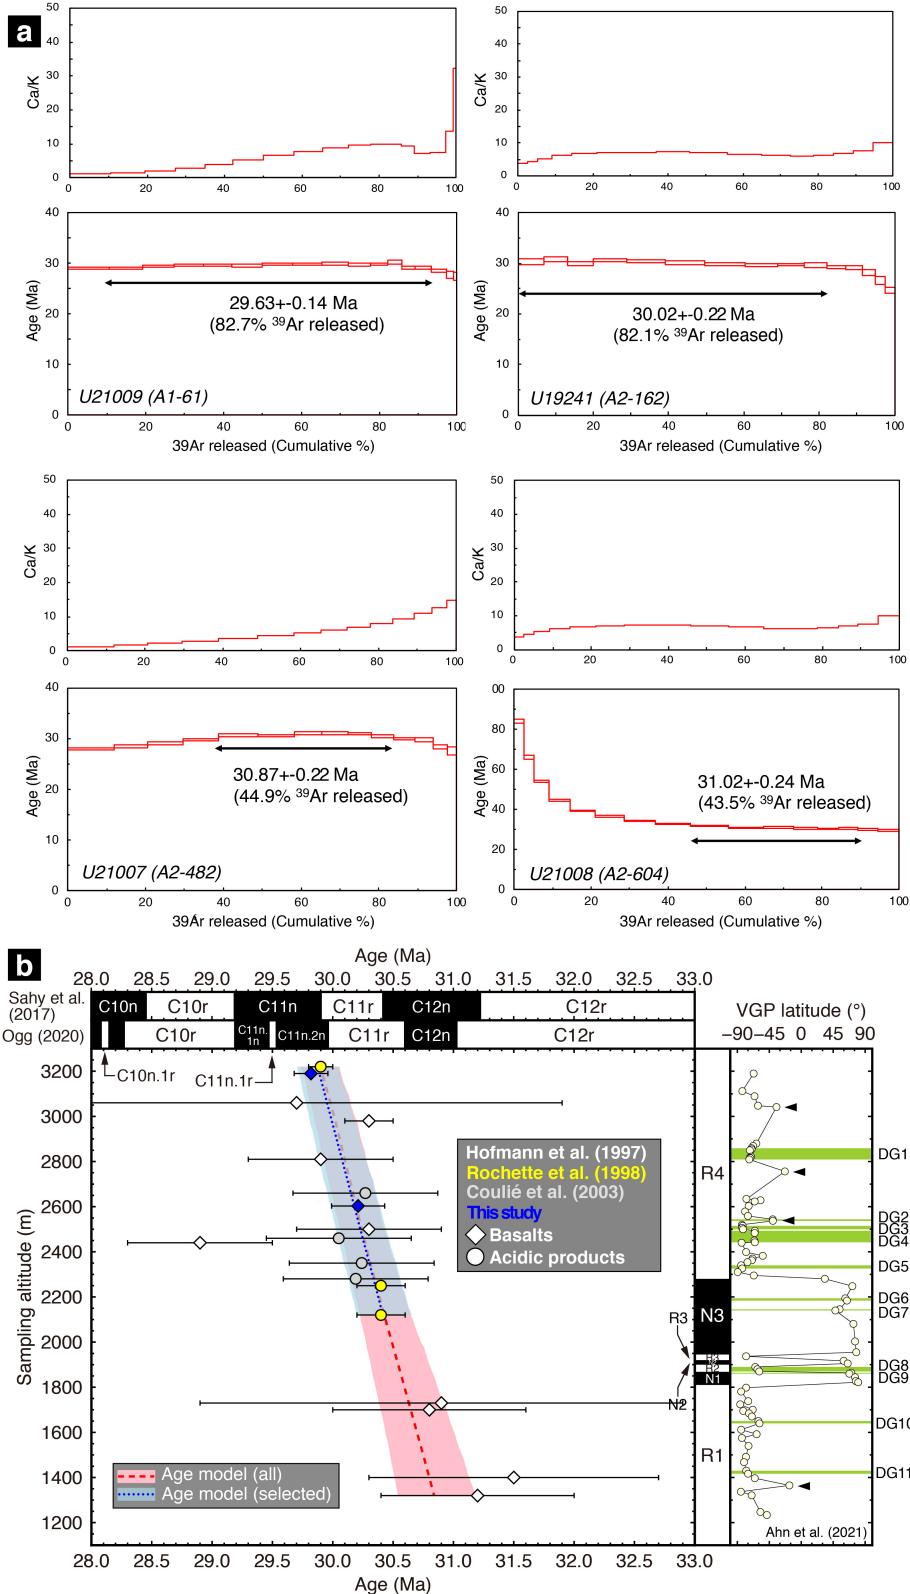

## 132        2.4 Eruption age model

133        We calculated Bayesian eruption age models using MacBacon 2.2 (Blaauw and Christen,  
134        2011) and applied the following prior distributions: acc.shape = 1.5; acc.mean = 500;  
135        mem.strength = 4, mem.mean = 0.7, thick = 125 (same as Sprain et al., 2019 except for the “thick”).

136        **3 Results**

137        Four samples were dated by stepwise heating analysis (Tables S1 and S2; Fig. 2a). Two  
138        samples (A1–61 and A2–162) yielded well-defined age plateaus comprising 82.7% and 82.1% of  
139        released gas, respectively (Tables S1 and S2; Fig. 2a). The inverse isochron ages for the two age  
140        spectra are identical to the weighted average ages of plateau-forming steps within  $2\sigma$  error (Table  
141        S1, Fig. S3). These data indicate that the two plateau ages ( $29.63 \pm 0.14$  Ma for sample A1–61 and  
142         $30.02 \pm 0.22$  Ma for sample A2–162) ( $2\sigma$ , respectively) are reliable eruption ages of the basalts.  
143        A2–482 showed a partially disturbed age spectrum comprising 44.9% of released gas and did not  
144        have a plateau in a strict mean (Tables S1, S2; Fig. 2a). Sample A2–604 gave an age spectrum  
145        comprising 43.5% of the released gas and did not exhibit a plateau in a strict mean either (Tables  
146        S1 and S2; Fig. 2a). The age spectrum includes some apparent disturbance in low-temperature  
147        steps due to  $^{39}\text{Ar}$  recoil (Schaen et al., 2020). Thus, we do not use the ages (samples A2–604 and  
148        A2–482) in our discussion.

149

150      **Figure 2.** (a)  $^{40}\text{Ar}/^{39}\text{Ar}$  age spectra and Ca/K plots for leached groundmass samples. Arrows  
151      indicate the steps forming plateau ages.  $^{40}\text{Ar}/^{39}\text{Ar}$  plateau ages are shown with  $2\sigma$  error. (b)

152 Bayesian eruption age models and compilation of our  $^{40}\text{Ar}/^{39}\text{Ar}$  ages for the Lima-Limo section  
 153 together with previously reported  $^{40}\text{Ar}/^{39}\text{Ar}$  ages (Hofmann et al., 1997; Rochette et al., 1997;  
 154 Coulié et al., 2003) with altitude ( $2\sigma$  error). The age model with the red dashed (blue dotted) line  
 155 and the pink (light blue) area is for all ages (selected ages: this study and Rochette et al., 1998).  
 156 The lines are averages of the age models, and the colored areas show 95% confidence intervals.  
 157 Bayesian age model Bacon (Blaauw and Christeny, 2011) was used. All  $^{40}\text{Ar}/^{39}\text{Ar}$  ages are  
 158 recalibrated to the FCs standard with an age of 28.201 Ma (Kuiper et al., 2008) and the  $^{40}\text{K}$  decay  
 159 constant (Min et al., 2000). The Lima-Limo magnetostratigraphy, VGP latitudes, and  
 160 paleomagnetic directional groups (DGs) (yellow green shaded boxes) (Ahn et al., 2021) (on the  
 161 right) and two GPTS models (Ogg, 2020; Sahy et al., 2017) (on the top) are also shown. The black  
 162 triangles indicate putative excursions Ahn et al. (2021) identified.

## 163 4 Discussion

### 164 4.1 Age correlation with geomagnetic polarity time scale

165 Here, we compare our high-precision groundmass-derived ages and the previously reported  
 166 high-precision sanidine single-crystal-derived ages (Rochette et al., 1998) with the geomagnetic  
 167 polarity ages of two GPTS models (Sahy et al., 2017; Ogg, 2020). The GPTS model of Ogg (2020)  
 168 is the latest version of the GPTS. This GPTS model provides ages of geomagnetic reversal  
 169 boundaries based on marine magnetic anomalies since the middle Mesozoic, which is constrained  
 170 by astronomical tuning. The GPTS model of Sahy et al. (2017) was constructed by minimizing the  
 171 discrepancy between the age-depth model based on U-Pb ages and the GPTS model of Ogg (2020).  
 172 All  $^{40}\text{Ar}/^{39}\text{Ar}$  ages here are recalibrated using the FCs standard with the age of 28.201 Ma (Kuiper  
 173 et al., 2008) and the  $^{40}\text{K}$  decay constant (Min et al., 2000) (Table S3). We can distinguish our two  
 174  $^{40}\text{Ar}/^{39}\text{Ar}$  ages (samples A1-61 and A2-162 from the R4 magnetozone) at the  $2\sigma$  level ( $29.82 \pm$   
 175  $0.14$  Ma and  $30.21 \pm 0.22$  Ma, respectively). The age of sample A1-61 is correspond to Chron  
 176 C11n.2n of GPTS2020, but this is not consistent with the polarity (Fig. 2b). In Sahy and other's  
 177 GPTS model, the age of sample A1-61 is consistent with Chron C11r age at the  $2\sigma$  level (Fig. 2b).  
 178 The previous high precision sanidine single-crystal age of the sample LLC ( $29.9 \pm 0.1$  Ma)  
 179 (recalibrated from Rochette et al., 1998) agrees with our age of sample A1-61 at almost the same  
 180 elevation (~3200 m), indicating that our groundmass age has the similar accuracy and precision as  
 181 the sanidine single-crystal age. Besides, the age of sample LLC agrees with Chron C11r of both  
 182 GPTS models at the  $2\sigma$  level (Fig. 2b) and the age of sample A2-162 agrees with Chron C11r of  
 183 both GPTS models (Fig. 2b). Given these, we can interpret that all of the reversed polarity lava  
 184 sequences at elevations between 2300 m and 3300 m (the R4 magnetozone) erupted in Chron C11r.

185 We can interpret that the Lima-Limo section erupted over Chrons C12r and C11r based on  
 186 the eruption age models calculated from radiometric ages compiled from this study and previous  
 187 studies (Fig. 2b, Table S4). This means that the Lima-Limo section erupted between 31.7 and 29.8  
 188 Ma (maximum estimation). The age model using our ages and the sanidine single-crystal ages of  
 189 Rochette et al. (1998), which have high precision, agree with the age model constructed from all  
 190  $^{40}\text{Ar}/^{39}\text{Ar}$  ages. This means that our ages and those of Rochette et al. (1998) contribute highly to  
 191 the the age model constraints. The top of the age model constructed from all ages (3220 m)  
 192 overlaps with Chron C11r of both GPTS models at the 95% confidence intervals, but it does not  
 193 overlap with Chron C11n.1r of both GPTS models. This indicates that the lava flow of the  
 194 magnetozone R4 erupted during Chron C11r. The N3–R4 magnetozone boundary of the age model  
 195 constructed from all ages (2280 m) overlaps with the C12n–C11r boundary of the GPTS model of

196 Sahy et al. (2017) at the 95% confidence interval level, while it does not overlap with the boundary  
 197 of Ogg (2020). The R1–N1 magnetozone boundary (1810 m) does not overlap with C12r–C12n  
 198 boundary at the 95% confidence intervals of both GPTS models. This discrepancy suggests that  
 199 the eruption rate around the R1–N1 magnetozone boundary may have been low. This possibility  
 200 is consistent with the results that there are lava flows with intermediate paleomagnetic directions  
 201 between the magnetozones N3 and R4, but not between R1 and N1 (Ahn et al., 2021). The bottom  
 202 of the age model constructed from all ages (1330 m) overlaps with Chron C12r of the GPTS model  
 203 of Ogg (2020) at the 95% confidence intervals, while it does not overlap with C12r of the GPTS  
 204 model of Sahy et al. (2017). This indicates that the lava flow of the magnetozone R1 erupted  
 205 during Chron C12r. In summary, the lava flows of the magnetozone R1 belong to Chron C12r, the  
 206 those of the magnetozones N1 to N3 belong to Chron C12n, and the those of the magnetozone R4  
 207 belong to Chron C11r. We have uniquely correlated the Lima-Limo section to the GPTS for the  
 208 first time.

209 We cannot correlate the short-lived reversed-polarity lava flows, R2 and R3 magnetozones  
 210 ('Lima-Limo reversals'), to Chron C12n of both GPTS models because Chron C12n does not  
 211 include cryptochrons or excursions on the current GPTS. We now consider two possibilities for  
 212 these reversed-polarity magnetozones. The first possibility is that we identified four new  
 213 geomagnetic reversals within Chron C12n that have not been previously detected from marine  
 214 magnetic anomalies (Cande and Kent, 1992). In this case, there would be a short reversal polarity  
 215 in Chron C12n that has not yet been registered in GPTS. In the Waja section that erupted in Chron  
 216 C12n (Eid et al., 2021), intermediate paleomagnetic directions were reported from six lava flows.  
 217 The six lava flows are located in the lower part of the Waja section, which suggests that the  
 218 paleomagnetic direction in early C12n is unstable. This finding is consistent with the R2 and R3  
 219 magnetozones found in the Lima-Limo section. A relative paleomagnetic intensity low in the early  
 220 C12n observed in Oligocene marine sediments (Yamazaki et al., 2013; Yamamoto et al., 2014)  
 221 may reflect the Lima-Limo reversals, suggesting that this is a global event. In addition, the absolute  
 222 paleointensity decrease was observed in the N1 magnetozone (Yoshimura et al., 2020). Thus, we  
 223 interpreted that geomagnetic reversals occurred in early Chron C12n. The second possibility is that  
 224 the lavas in the R2 and R3 magnetozones are intrusive rocks formed at different times than the  
 225 upper and lower lava. When we conducted the field survey at the Lima-Limo section, however,  
 226 we did not find any dyke or sill in the lava outcrops (Fig. S1). Therefore, we consider that the  
 227 geomagnetic reversals of the R2 and R3 magnetozones reflect the geomagnetic field behavior in  
 228 early Chron C12n.

#### 229 4.2 Estimation of emplacement rate

230 We calculate the eruption rate for each chron to calculate the eruption rate using the volume  
 231 of 150000 km<sup>3</sup> of tholeiitic basalt in the LT basalt zone estimated in a previous study (Beccaluva  
 232 et al., 2009). This is about 20% of the total volume of the Ethiopia–Yemen Traps (Rooney, 2017)  
 233 of 720000 km<sup>3</sup>. In this case, the volume of magnetozone R4 is calculated to be 71484 km<sup>3</sup>, N1 to  
 234 N3 is 31524 km<sup>3</sup>, and R1 is 46992 km<sup>3</sup>. We assume that the maximum eruption durations are as  
 235 follows: 0.621 Myr (Ogg, 2020) or 0.50 Myr (Sahy et al., 2017) for the R4 magnetozone (Chron  
 236 C11r), 0.386 Myr (Ogg, 2020) or 0.82 Myr (Sahy et al., 2017) for the N1 to N3 magnetozones,  
 237 and 2.237 Myr (Ogg, 2020) or 1.86 Myr (Sahy et al., 2017) for the R1 magnetozone. Based on  
 238 these maximum durations, the eruption rates are calculated as 0.02 to 0.03 km<sup>3</sup>/yr for the R1  
 239 magnetozone, 0.04 to 0.08 km<sup>3</sup>/yr for the N1 to N3 zone, and 0.12 to 0.14 km<sup>3</sup>/yr for the R4  
 240 magnetozone, respectively (Table S5). Note that it is unclear when the eruption of the R1

241 magnetozone began. According to our age model, the lavas of the magnetozone R1 are likely to  
 242 start eruption in late Chron C12r (Fig. 2b). However, this inference is not precise enough to  
 243 calculate the eruption rate of the R1 magnetozone. Therefore, it is also necessary to estimate the  
 244 eruption rate in the paleomagnetic directional groups (DGs).

245 To determine the net duration of the eruptive period of the Lima-Limo section, we use the  
 246 results of the analysis of paleomagnetic secular variations recorded in the section (Ahn et al., 2021).  
 247 Ahn et al. (2021) used the method proposed by Mankinen et al. (1985) and the statistical test of  
 248 McFadden and Lowes (1981). They then grouped the statically same directions and assigned 11  
 249 DGs. However, site-averaged directions with  $\alpha_{95}$  exceeding ten were used for two DGs, so only  
 250 nine DGs are used in this study. We assume that the rate of geomagnetic secular variations in the  
 251 last 3000 years ( $\sim 2^\circ/100$  years, Chenet et al., 2008) and that in the Lima-Limo section are the  
 252 same. Because lava flows record the ambient geomagnetic direction during cooling, we can infer  
 253 whether the paleomagnetic directions of successive lava flows were separated by long time  
 254 intervals using paleomagnetic secular variations. Lava flows separated by long time intervals  
 255 usually have significantly different mean paleomagnetic directions, but when erupted successively  
 256 within a short time interval, such as 100 years, they are statistically indistinguishable. If the mean  
 257 directions of adjacent lava flows are statistically indistinguishable at the 95% confidence level, the  
 258 lava flows are considered to have been rapidly emplaced and failed to record paleomagnetic secular  
 259 variations. Their paleomagnetic directions are merged into a single DG (Chenet et al., 2008). We  
 260 assumed the upper and lower limits of lava eruption time for individual DGs as 100 years and ten  
 261 years, respectively, and the interval of lava flows that have distinct paleomagnetic directions as at  
 262 least 500 years (Chenet et al., 2008). In this case, for the entire Lima-Limo section, the eruption  
 263 period of the R1 magnetozone corresponding to Chron C12r is  $2 \times 10 (100) + 20 \times 500 = 10020$   
 264 (10200) years at least (at most). Through the same calculation manner, that of the N1 to N3  
 265 magnetozones is 7010–7100 years, and that of the R4 magnetozone is 11550–12000 years. The  
 266 eruption rates can be estimated to be 4.61–4.69 km<sup>3</sup>/yr for the magnetozone R1, 4.44–4.50 km<sup>3</sup>/yr  
 267 for the magnetozones N1 to N3, and 5.96–6.19 km<sup>3</sup>/yr for the magnetozone R4, respectively (Table  
 268 S5). Note that the relatively high eruption rate of the magnetozone R4 would be slightly  
 269 overestimated because sampling densities were sparse due to poor exposures at  $\sim 2640$ –2740 and  
 270  $\sim 2900$ –3040 m and entrance restrictions at 3120–3260 m (Ahn et al., 2021). Nevertheless, these  
 271 rates are lower than the previous estimation for HT2 lavas (4–13 km<sup>3</sup>/yr: Eid et al., 2021).

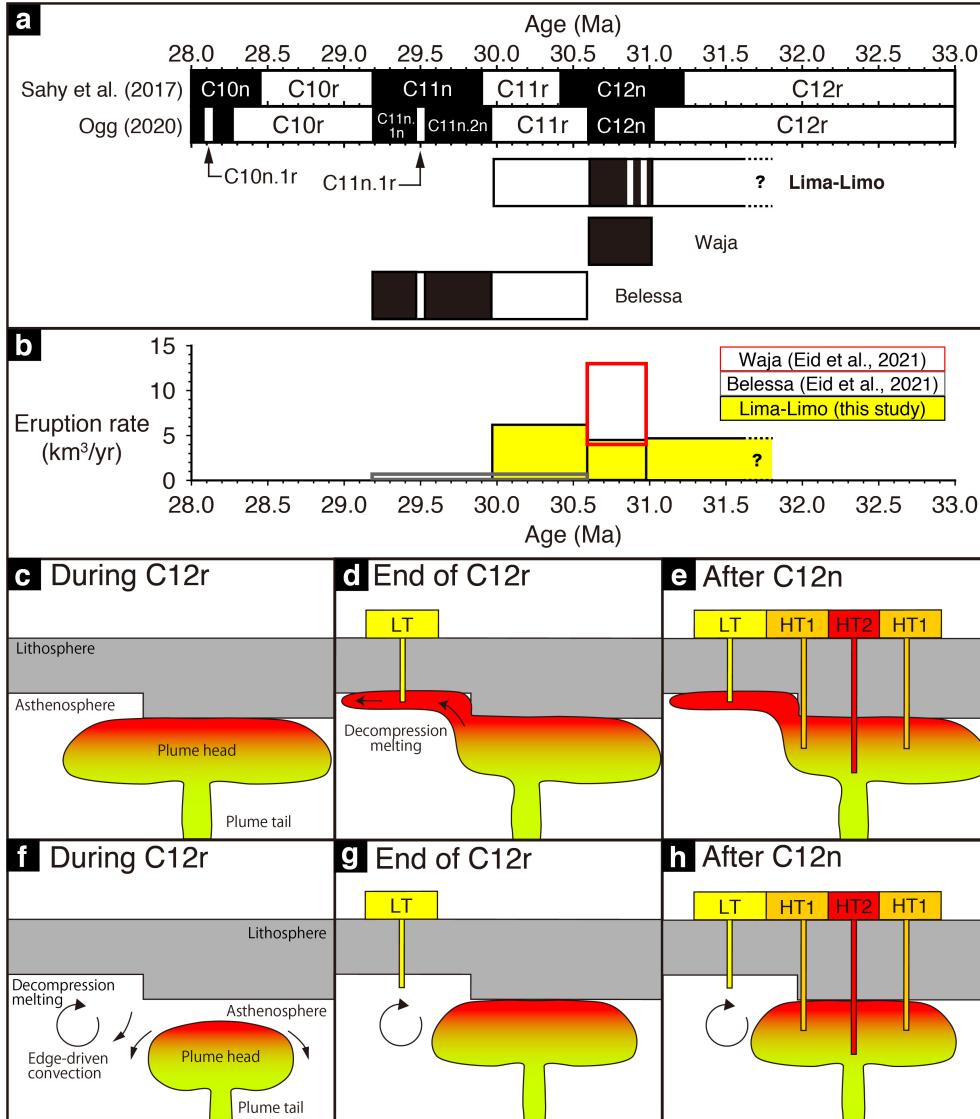

272       4.3 Edge-driven convection to induce partial melting of ambient (non-plume)  
 273            asthenosphere

274 The HT2 lavas reported in a previous study (Pik et al., 1998) are thought to represent the  
 275 mantle plume axis (Natali et al., 2016). The HT2 lava flows were the first zone to erupt in three  
 276 titanium zones and had the highest emplacement rate of 4–13 km<sup>3</sup>/yr in the Oligocene Ethiopia–  
 277 Yemen Traps, which is thought to be the Afar plume head expression (Eid et al., 2021). The HT1  
 278 zone shows a circular pattern around the HT2 zone (Fig. 1a) (Beccaluva et al., 2009; Natali et al.,  
 279 2016). The mantle potential temperatures of each zone are consistent with the expected plume head  
 280 temperature distribution (Beccaluva et al., 2009; Natali et al., 2016). However, we found that the  
 281 LT lavas erupted earlier than the HT2 lavas and had a lower eruption rate than the HT2 lavas (Fig.  
 282 3a, b). In other words, the LT zone would have been the first eruption in the Oligocene Ethiopia–  
 283 Yemen Traps, even though it was not on the plume head axis. Additionally, the emplacement rate  
 284 of the LT lavas was lower than that of the HT2 lavas. Given that the Lima-Limo and Belessa  
 285 section, the eruption period of the LT lavas (Chron C12r to C11n.1n) appears to have been

286 significantly longer than that of the HT2 lavas (Chron C12n) (Fig. 3a). These results are contrary  
287 to the geodynamic model which predicts that the first stage of the plume eruption is the most  
288 vigorous. If the plume head collides with a lithosphere with a simple structure, then eruptions  
289 caused by the plume head should be spatially simultaneous. However, this is not the case in the  
290 Afar region.

291 We propose that this discrepancy in eruption timing was caused by the interaction of the  
292 Afar plume with the lithospheric basement topography. The first scenario is that a part of the plume  
293 reached the near-surface earlier than the plume head axis. When there is a gradient of the  
294 lithospheric thickness (i.e., lithospheric step), the plume would flow and rise along the lithospheric  
295 step from a thicker part to a thinner part (e.g., Thompson and Gibson, 1991; Ebinger and Sleep,  
296 1998; Gorczyk et al., 2018). In the Afar plume case, we assume that the lithosphere under the LT  
297 zone was thin, and the lithosphere under the HT2 zone was thick. It is difficult to verify the  
298 lithospheric step under the Afar basement that once may have existed because the lithospheric  
299 thickness at present is considered to have been increased by the Afar plume accretion.  
300 Nonetheless, this is possible because the lithospheric thickness can have large spatial variations  
301 (e.g., Globig et al., 2016). After the Afar plume collided with the lithosphere, a part of the plume  
302 flowed into the thinner lithosphere under the LT zone (Fig. 3c–e). This induced decompression  
303 melting of the asthenosphere to produce the HT magma. However, little plume signals have been  
304 found in the LT lava (Marty et al., 1996; Pik et al., 2006). Thus, the flood basalts in the LT zone  
305 may not be explained by the decompression melting of the plume head. The second scenario is  
306 that edge-driven convection occurred when the Afar plume rose (Fig. 3f–h). Edge-driven  
307 convection is an asthenospheric small-scale convective instability caused by lithospheric steps (e.g.,  
308 King and Anderson, 1998). Numerical simulations suggested that edge-driven convection  
309 presumably occurred at a lithospheric step near the plume before the collision of the plume at the  
310 lithosphere–asthenosphere boundary (Duvernay et al., 2022); when a lithospheric step between the  
311 LT and HT2 zones was present, edge-driven convection would have induced partial melting of the  
312 ambient (non-plume) asthenosphere to produce LT magma (Fig. 3g). Also, this scenario is  
313 consistent with little plume signal found in the lavas of the LT zone. Furthermore, we can explain  
314 the lower emplacement rate of the LT lavas than that of the HT2 lavas because the emplacement  
315 was not caused by the impact of the main body of the plume head (Fig. 3b). This scenario can  
316 successfully explain the absence of LT lavas in the eastern part of the East African Main Rift and  
317 the Yemen area (Pik et al., 1998) and the asymmetric shape of the Afar plume (Beccaluva et al.,

318 2009). The interaction between the mantle plumes and the continental lithospheric geometry in the  
 319 scenario may occur universally when a plume rises.

320 **Figure 3.** (a) Emplacement order of the Lima-Limo, Waja, and Belessa sections with the  
 321 geomagnetic polarity time scales (Sahy et al., 2017; Ogg, 2020). (b) Eruption rates of each section.  
 322 (c–e) Schematic illustration of the Afar plume rise and emplacement of the Traps by the  
 323 decompression melting. (c) The Afar plume collides with the lithosphere. (d) A part of the Afar  
 324 plume flows into the thinner lithosphere. The part of the plume rises along the lithosphere, which  
 325 causes decompression melting. (e) Subsequently, the hot plume head center melts, which forms  
 326 the HT1 and HT2 basalts. We assume that HT1 and HT2 erupted simultaneously. (f–h) Schematic  
 327 illustration of the Afar plume rise and emplacement of the Traps by edge-driven convection. (f)  
 328 When the Afar plume approaches the surface, edge-driven convection occurs near a lithosphere  
 329 step. Edge-driven convection causes decompression melting of ambient (non-plume)  
 330 asthenosphere. (g) The decompression melting produces the first magma of the Oligocene Afar

331 plume, the LT lavas. (h) Subsequently, the hot plume head center melts, which forms the HT1 and  
 332 HT2 basalts.

### 333 **5 Conclusion**

334 We conclude that the Oligocene Ethiopia–Yemen Traps in the Lima-Limo section erupted over  
 335 Chrons C12r–C12n–C11r considering new high-precision  $^{40}\text{Ar}/^{39}\text{Ar}$  ages and previously reported  
 336  $^{40}\text{Ar}/^{39}\text{Ar}$  ages. The four geomagnetic reversals observed in the Chron C12n lava flow may be  
 337 short geomagnetic reversals within Chron C12n. The LT lavas in the Lima-Limo section emplaced  
 338 before the main pulse of Afar magmatism, the eruption of the HT2 lavas. The eruption rate of the  
 339 Lima-Limo section was lower than that of HT2 lavas. Since little plume component is detected for  
 340 the LT lavas, we suggest that the partial melting of ambient (non-plume) asthenosphere to produce  
 341 the LT magmas was induced by edge-driven convection in the asthenosphere, which occurred  
 342 before the plume head reached the lithosphere.

### 343 **Acknowledgements**

344 We thank Yusuke Suganuma, Kenichiro Tani, Hironao Matsumoto, Masakazu Fujii, Naoto  
 345 Fukuyo, and Takashi Sano for their helpful suggestions. We thank Ryo Okumura, Hisao

27 inverse isochron plots]

28

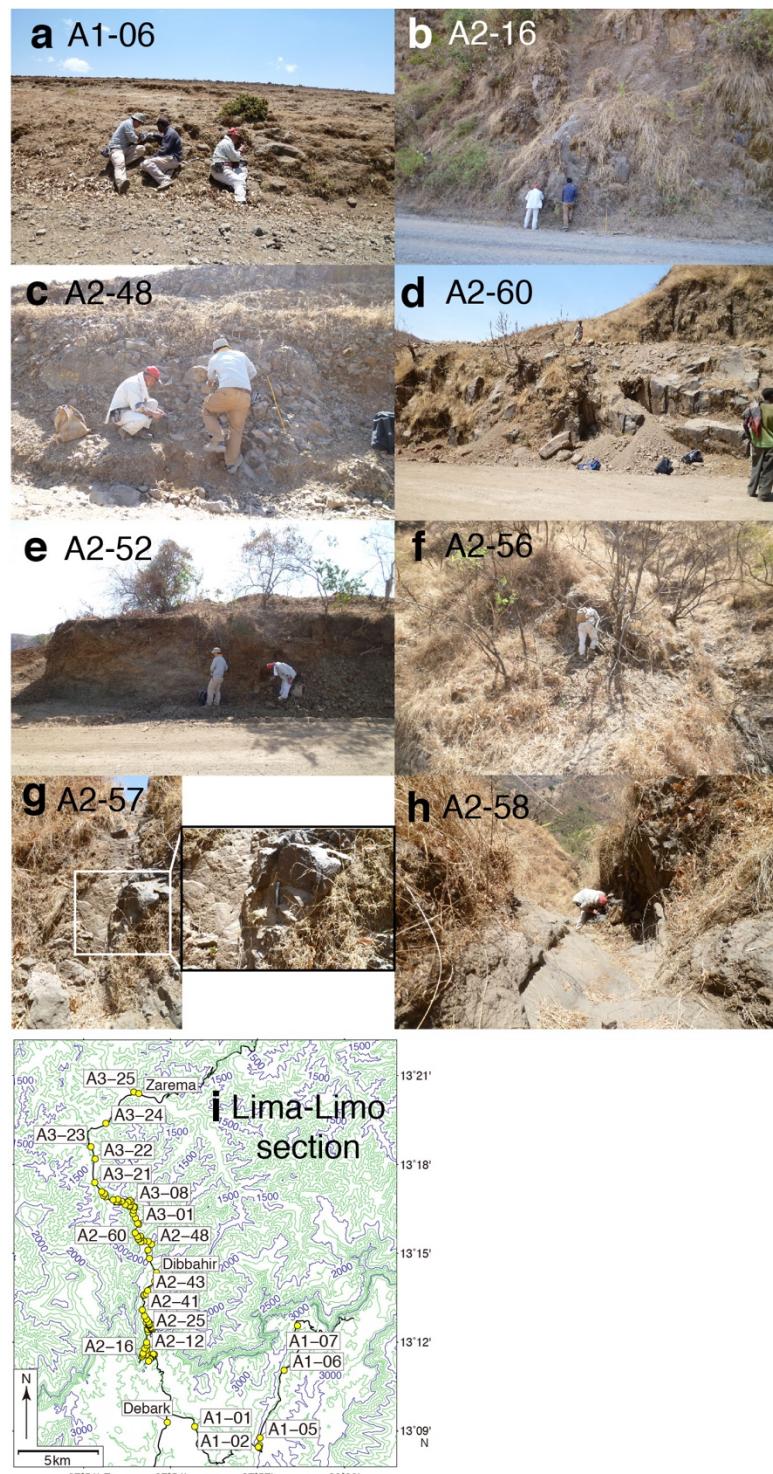

29 **Text S1.  $^{40}\text{Ar}/^{39}\text{Ar}$  dating**

30 We analyzed 7.3-8.8 mg of phenocryst-free groundmass using a step-wise heating procedure,  
31 which was crushed and sieved to 250-500  $\mu\text{m}$  in size. We prepared groundmass grains using  
32 the SELFRAG Lab system at the National Museum of Nature and Science, Tsukuba. We treated  
33 the samples in 6N HCl for 30 minutes and then 4N  $\text{HNO}_3$  for 30 minutes at 95°C with stirring to  
34 clean up any secondary products (clays and carbonates) existing in interstitial spaces. After the  
35 treatment, we removed microphenocrysts of clinopyroxene in the samples under a  
36 microscope. Sample irradiation was done at the reactor of the Institute for Integrated  
37 Radiation and Nuclear Science, Kyoto University for four hours. We used sanidine separated  
38 from the Fish Canyon Tuff (FC3) for the flux monitor and assigned it an age of 27.5 Ma, which  
39 was determined against our primary standard for our K-Ar laboratory, Sori biotite, whose age  
40 is 91.2 Ma (Uchiumi & Shibata, 1980).

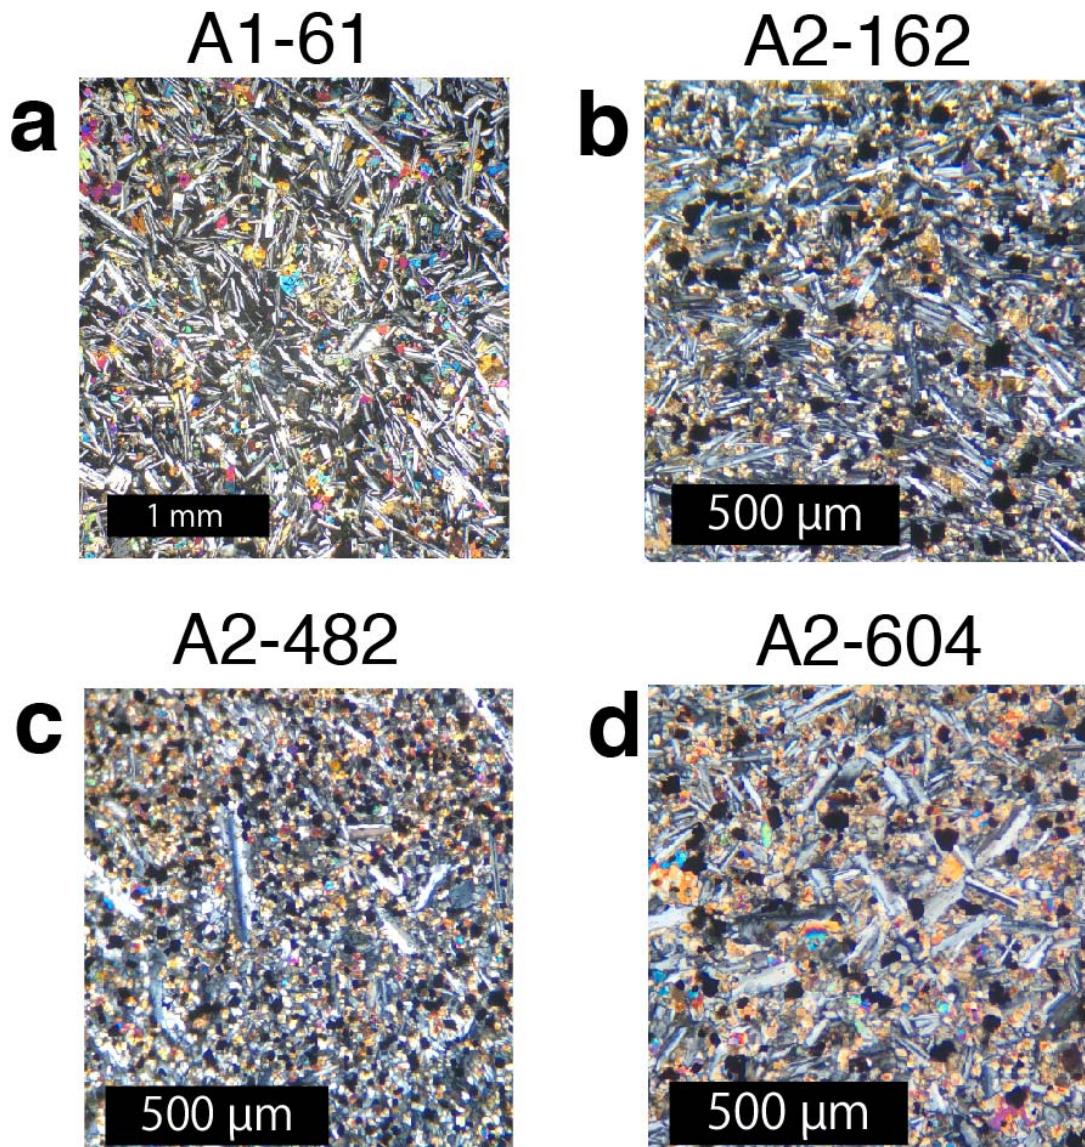

41  
42 We used a  $\text{CO}_2$  laser heating system (NEWWAVE MIR10-30) at continuous wave mode for  
43 sample heating. We used a faceted lens in order to obtain a 3.2 mm-diameter beam with  
44 homogenous energy distribution to ensure uniform heating of the samples during stepwise  
45 heating analysis. We measured argon isotopes on an IsopopX NGX noble gas mass  
46 spectrometer fitted with a Hamamatsu Photonics R4146 secondary electron multiplier in a  
47 peak-jumping mode.

48  
49 Errors for  $^{40}\text{Ar}/^{39}\text{Ar}$  results are reported at one standard deviation ( $1\sigma$ ) in Fig. S3, Tables S1 and  
50 S2. In the main text, errors are reported at two standard deviations ( $2\sigma$ ). Errors for ages include  
51 analytical uncertainties for Ar isotope analysis, correction for interfering isotopes and J value  
52 estimation. We achieved correction for interfering isotopes by analyses of  $\text{CaF}_2$  and  $\text{KFeSiO}_4$   
53 glasses irradiated with the samples. We assigned an error of 0.5% to J values as a pooled  
54 estimate during the course of this study. Results of Ar isotopic analyses and correction factors  
55 for interfering isotopes are presented in Table S2.

56  
57 We calculated plateau ages as weighted means of ages of plateau-forming steps, where each  
58 age was weighted by the inverse of its variance. We determined the age plateaus following  
59 the definition by Fleck et al. (1977). We calculated inverse isochrons using York's least-squares  
60 fit, which accommodates errors in both ratios and correlations of errors (York et al., 2004).

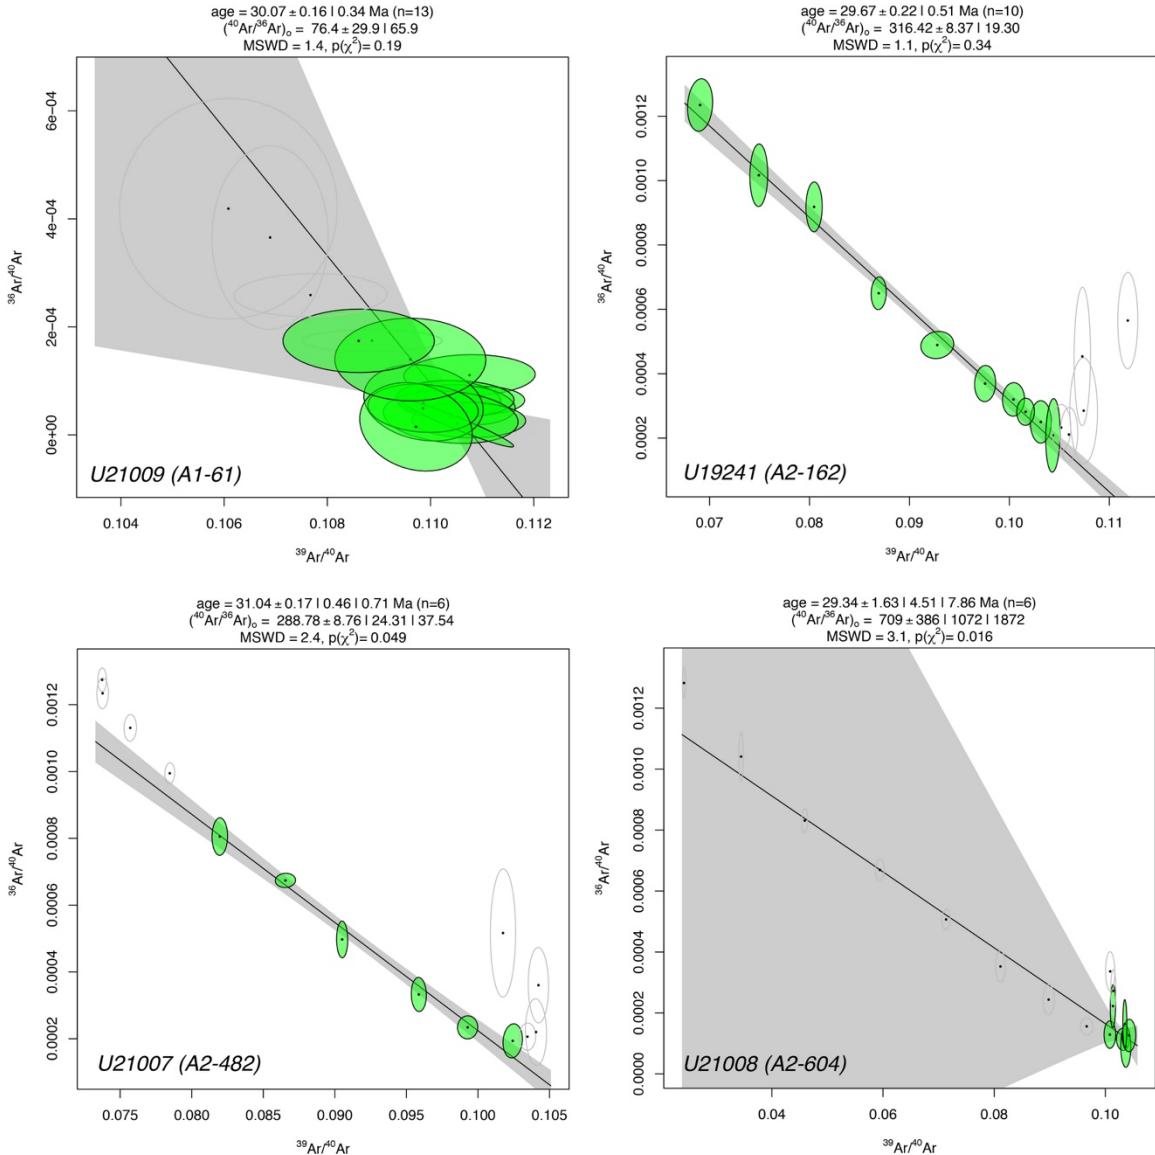

62 **Figure S1.** (a-h) Field photograph of basaltic flow at site A1-06, A2-16, A2-48, A2-60, A2-52, A2-  
 63 56, A2-57, A2-58. (i) Route map of the sampling sites (solid yellow circles) in the Lima-Limo  
 64 section.

**Figure S2.** (a-d) Thin section of samples A1–61, A2–162, A2–482, and A2–604 (crossed nicols), which are samples from the lava flows where  $^{40}\text{Ar}/^{39}\text{Ar}$  datings were conducted in this study. There are (a) crystalline groundmass and (b-d) fine grain groundmass with plagioclase phenocrysts and microphenocrysts of opaque minerals.

72  
73

74 **Figure S3.** Plots of the inverse isochrons are plotted from each respective  $^{40}\text{Ar}/^{39}\text{Ar}$   
75 experiment. Solid black lines are the best estimated inverse isochrons. Ovals express 1-sigma  
76 error ellipses for each incremental heating step.

**Table S3.** Recalibrated  $^{40}\text{Ar}/^{39}\text{Ar}$  ages of this study and previous studies for the Lima Limo section, Ethiopia.

Sample ID, original sample name therein from the literature. Pol., geomagnetic polarity determined in the original literature;  $^{40}\text{Ar}/^{39}\text{Ar}$  (recalibrated), recalibrated  $^{40}\text{Ar}/^{39}\text{Ar}$  age estimate (in Ma) using the updated  $^{40}\text{K}$  decay constant (Min et al. 2000) and FCs standard with an age of Kuiper et al. (2008), with its  $2\sigma$  uncertainty; Std, standard originally used as the neutron fluence monitors for  $^{40}\text{Ar}/^{39}\text{Ar}$  dating; Ref, reference of age data. Blank means "no data" or "no applicable". We recalibrated  $^{40}\text{Ar}/^{39}\text{Ar}$  ages of A1-61 and A2-162 in this study, while Ahn et al. (2021) recalibrated the others.

Locality	Sample ID	Altitude (m)	Rock type	Pol.	$^{40}\text{Ar}/^{39}\text{Ar}$ plateau (recalibrated)			$^{40}\text{Ar}/^{39}\text{Ar}$ plateau (original)			Ref
					Age	$2\sigma$	Age	$2\sigma$	Std
