 2 **seasonal halocline: 1975 versus 2006-2012”**

3 **1. Isolating  $\delta\Phi$  and  $\delta D$**

4 Here we provide the algebraic derivation of the equations 20-21, using the definitions provided  
 5 in Section 3a. First, the mixed-layer freshening ( $\mathbb{S}$ ):

$$\begin{aligned}
 \mathbb{S}_{ITP} &= \frac{\Phi_{ITP}}{D_{ITP}} \\
 &= \frac{\Phi_{AJX} + \delta\Phi}{D_{AJX} + \delta D} \\
 &= \mathbb{S}_{AJX} \left( \frac{1 + \delta\Phi/\Phi_{AJX}}{1 + \delta D/D_{AJX}} \right) \\
 &= \mathbb{S}_{AJX} (1 + \delta\Phi/\Phi_{AJX}) (1 - \delta D/D_{ITP}) \\
 &= \mathbb{S}_{AJX} + \frac{\Phi_{AJX}}{D_{AJX}} \left( \frac{\delta\Phi}{\Phi_{AJX}} - \frac{\delta D}{D_{ITP}} - \frac{\delta\Phi\delta D}{\Phi_{AJX}D_{ITP}} \right) \\
 \delta\mathbb{S} &= \frac{\delta\Phi}{D_{AJX}} - \frac{\Phi_{AJX}\delta D}{D_{AJX}(D_{AJX} + \delta D)} - \frac{\delta\Phi\delta D}{D_{AJX}(D_{AJX} + \delta D)}.
 \end{aligned}$$

6 Second, the potential energy anomaly ( $\mathbb{W}$ ):

$$\begin{aligned}
 \mathbb{W}_{ITP} &= C\Phi_{ITP}(H - D_{ITP} - Z_{ice}) \\
 &= C(\Phi_{AJX} + \delta\Phi) \cdot (H - D_{AJX} - \delta D - Z_{ice}) \\
 &= C\Phi_{AJX}(1 + \delta\Phi/\Phi_{AJX}) \cdot ((H - D_{AJX} - Z_{ice}) - \delta D) \\
 &= (1 + \delta\Phi/\Phi_{AJX}) \cdot (\mathbb{W}_{AJX} - C\Phi_{AJX}\delta D) \\
 \delta\mathbb{W} &= C((H - D_{AJX} - Z_{ice})\delta\Phi - \Phi_{AJX}\delta D - \delta\Phi\delta D)
 \end{aligned}$$

7 where we have defined  $C \equiv \rho_0\beta g/2$ .

## 8 **2. Uncertainties in $\Phi$ and $sFWC$**

9 Here we roughly estimate uncertainties in  $\Phi$  and  $sFWC$  due to a lack of near-surface mea-  
10 surements. First, we consider the thin, fresh surface layer that can emerge in during the sum-  
11 mer months. Proshutinsky et al. (2009) estimated that this bias causes the freshwater content  
12 (referenced to 34.8 psu) to be underestimated by 0.15-0.20m in the top 8m of the ITPs during  
13 June-August. If we consider the ITP-average  $S_0 = 27.78$  g/kg, this bias would correspond to an  
14 underestimate of 5.22-6.96 m·g/kg in  $\Phi$  (multiply 0.15-0.20 m by 34.8) and 0.19-0.25 m in  $sFWC$   
15 (as defined in Section 3; divide 5.22-6.96 m·g/kg by 27.78 g/kg).

20 **LIST OF FIGURES**

21 **Fig. S1.** Salt deficit ( $\Phi$ ) using two different methods for computing  $S_0$  with (left) AIDJEX and (right)  
22 ITP data. Blue and red lines indicate results setting  $S_0$  to the average-May surface salinity for  
23 the same ITP or AIDJEX ice camp during the same year (as in the main text). Black dashed  
24 lines indicate results from setting  $S_0$  to the average surface salinity during May 16-22 (the  
25 earliest 7-day period with all AIDJEX ice camps collecting data). Solid lines indicate 5-day  
26 averages and shading indicates one standard deviation. . . . . 5

27 **Fig. S2.** As in Figure 10 in the main text but using  $H = 20$  m, 33 m, and 40 m, respectively. Larger  
28 values of  $H$  yield larger differences between the ITP and AIDJEX data because differences  
29 in the winter halocline are incorporated. . . . . 6

30 Fig. S1. Salt deficit ( $\Phi$ ) using two different methods for computing  $S_0$  with (left) AIDJEX and (right) ITP  
 31 data. Blue and red lines indicate results setting  $S_0$  to the average-May surface salinity for the same ITP or  
 32 AIDJEX ice camp during the same year (as in the main text). Black dashed lines indicate results from setting  
 33  $S_0$  to the average surface salinity during May 16-22 (the earliest 7-day period with all AIDJEX ice camps  
 34 collecting data). Solid lines indicate 5-day averages and shading indicates one standard deviation.

35 Fig. S2. As in Figure 10 in the main text but using  $H = 20$  m, 33 m, and 40 m, respectively. Larger values  
 36 of  $H$  yield larger differences between the ITP and AIDJEX data because differences in the winter halocline are  
 37 incorporated.
